In this paper I purpose to dwell exclusively on my method of treating the lesions and functional derangements of the heart in old age.

Naturally, with the term "old age," there is pictured in the mind the infirmities and decrepitude of accumulated years: the coldness of withered fingertips, the odor of decay accompanying lack of oxygen from the weakened circulation, due to the worn-out organ which has labored so faithfully for threescore years and ten.

Yet this is not invariably the condition. Time can only be computed by externals; organically, a man may live, develop, enjoy, suffer, linger and die of old age at 45. Circumstances—the most finite of all things—alone determine our length of days, and the period at which we shall begin to deteriorate. Much, very much depends upon our environments; the strain to which this mortal machine has been subjected, and the degree of mental force expended. Given, an ordinarily healthy man's body, his capacity for endurance is determined by habits of life, manner of living, and general trend of thought.

It has been the popular opinion in order that a man may live out his full number of years that the heart must be strong in the beginning. When the human being comes into the world our first solicitude is for the heart; it is our key to all phenomena of strength and weakness. From birth throughout his progressive development of childhood, adolescence, middle age and decay, our finger is on the wrist, our ear at the chest.

What is the typical "senile heart" and by what signs may we recognize it? A thorough distinction between physiologic and pathologic changes must here be made. Physiologically, the heart in old age seems naturally to resume certain conditions which it lost with childhood, the most common of which may be seen in the quickened pulsations.

The familiar comparison of the heart to the size of the person's fist would be as inappropriate in old age as it is in infancy. While this enlargement as found in old age may generally be classed as a pathologic condition, to which we give the name "hypertrophy," we must remember that it is not an invariable indication of heart-failure. Again, as in the blood vessels: in infancy the coats are thin and frag-

ile, rendering them susceptible of rupture. In old age we meet with pathologic conditions which bring about very similar results, by loss of elasticity of the coats of vessels; rendering them friable, with consequent liability to rupture.

In the first instance—that of the infant—we have a physiologic condition, coming, if I may be allowed to so express myself, from physiologic functioning in an immature organ or system, while in the latter case—that of old age—we meet with tissue that has been worn out or weakened by long use, or improper treatment; "the muscular fibers becoming weary with too much work, or impoverished by scanty nutrition;" the debility being brought about by various means. Unnatural demands upon the contractile fibers of the heart bring about the features of cardiac senility, let the age be what it may.

We might theoretically claim that the heart would never cease its pumpings if the motive power supplied by the contractions of its muscular fibers were never lost. But heart tissue, as with all striated tissue, fails after awhile to respond to exorbitant demands, or it may become exhausted from mal-nutrition. By this it may be seen that heart failure may arise in itself, on account of impairment of its nervous or muscular elements, or by reason of some mechanical impediment to its workings, or, as Foster tells us, "by nervous influences proceeding from the brain, or brought into operation by means of the central nervous system."

In old age the alterations in structure of the walls of the blood vessels are always in evidence.

### TREATMENT.

Three factors,—which from their close relation are of equal importance, enter into the treatment of the senile heart, viz., diet, rest, and medicine. Let us consider the

*Diet.*—With increasing years we generally find a cessation of the ordinary stomach troubles which are so common in early life, and with their disappearance we have consequent increase of appetite, by the indulgence of which the fat-producing powers of the tissues are increased and their power becomes weakened thereby; the muscular fibers of the heart suffering from the same fatty degeneration which all muscular tissue undergoes when subjected to like conditions, and as the excess of general nutrition calls for extra exertion on the part of the heart which the weakened fibers are unable to accomplish, the result is dilatation and irritability of the heart substance.

Excessive eating and drinking is fatal in cardiac troubles. We find the person complaining of breathlessness after taking sufficient food and drink to satisfy his voracious appetite, and he is glad to lie down and keep quiet for an hour or two, until the pressure has subsided. Fortunate the person who has led an abstemious life, for the sacrifice will not be so great. The gourmand will tell you that he would forfeit several years from his life rather than relinquish the pleasures of the festive board and adopt the rigid diet his condition demands; for there can be no cardiac disturbance after middle life which does not call for total abstinence from all undue indulgence of physical appetite.

Our investigations should not begin or end with the heart alone; they must include the habits of the individual; the everyday things which go to make up

the person's sum of living—mentally as well as physically—for at this period of near approach to absolute knowledge it would be absurd, and indeed a most abject admittance on the part of the physician or physiologist to deny the close relations existing between the mind and body, or to ignore their interdependence upon each other for the perfect health of either, or that the body can be in healthy poise with the mind ill at ease. Objective conditions can never be separated from the subjective; as we wrestle with the problems which deal with our physical man, the mental is equally squaring itself with the vital organism.

The young plant, with its superabundance of vitality will grow and develop almost without sunshine, and with sparsity of soil. It is after the plant has passed maturity, and the sap of vitality runs slowly, and the electrical principle is on the wane, that we are called upon to protect it and give it artificial support. At this period we may look for parasitic growths and unhealthy phenomena. So it is with the living animal organism. While development is going on, the organic powers are, in the untainted body, equal to all physiologic requirements. It is after the fires of life have lost their sparkle and the animal powers are running low, that we may look for organic lesions,—especially of the heart. Energy and life may be considered synonymous terms, and nature never intended that either one should terminate abruptly. We are the *alter ego* of nature, and no natural phenomena begins or ends abruptly.

In the details of our treatment we must be guided by the various symptoms as they present themselves. Stimulants, so generally recommended in the weakened condition of the aged are, as a rule, to be avoided. In edema, all liquids which are not absolutely necessary to quench the thirst of the patient must be withdrawn; and the periods between meals of sufficient length to prevent any encroachment upon active digestion by a fresh relay of food. In cardiac weakness, digestion goes on less rapidly from insufficiency in quality and quantity of the gastric juice, hence the periods between meals must be longer than when in health, and less food should be taken at a time. Let the heartiest meal be at noon, and the lightest at night. Cardiac troubles of themselves often create an abnormal appetite, and this, together with the fact that our most frequent sufferers are those naturally fond of the good things of the table, renders regulation of the diet the most difficult thing for the physician to carry out. Even the specter of sudden death loses its power to frighten the victim of an abnormal growing hunger.

*Food.*—No matter what the patient's habits may have been, I take from the *menu* all condiments and stimulating foods, all fruits unless they go to form part of the regular meal, also all vegetables with the exception of small quantities of mealy baked potatoes, eaten with cream or milk. Vegetables are composed of more or less water and woody fiber, are bulky, and fill the stomach and bowels with gas; their nutritive qualities do not compensate for the space they occupy.

While we can not (and it would be unwise for us if we could) treat our patients like so many machines, to be fed at will, we must yet insist upon regularity as to the time their meals shall be taken.

Flint says words to the effect that the man who closely watches his digestion, timing every article of

food which he puts into his stomach, as it is being acted upon by gastric digestion, watching its progress from thence outward, never escapes being a victim of dyspepsia. From this, as well as other reasons, I hold no argument with my patient as to what he shall eat, or in what manner it shall be prepared, but simply put before him certain rules—verbally or in writing—which he is to follow, and these need not necessarily be so limited as to give him any real cause for complaint.

Probably the total withdrawal of tobacco in any form will cause as much rebellion from our male patients, as any deprivation in the way of food or drink.

Just before meals a teaspoonful of bovinin in a tablespoonful of water is a most excellent adjunct to the food, increasing the flow of gastric juice and obviating flatulency. Raw oysters may be eaten, but should not constitute the meal. Of fish, we have cod, halibut, shad, perch, and pickerel broiled, with butter sparingly. Of fresh meats, sirloin steak well done, with a little butter, chopped beef with one-tenth of fat breakfast bacon, poultry, pigeons and game. All meats should be recently slaughtered, and all fish freshly caught. The cooking should be done expeditiously. With the meat and fish may be eaten such relishes as watercress in its season, dandelion greens, spinach, asparagus and celery, in very small quantities. A small amount of baked sour apple may be eaten with the evening meal with bread and butter and a teaspoonful of pineapple juice as a digester. The honeycomb part of tripe broiled will be an acceptable change to the diet occasionally, if the patient likes it. Bread should form a considerable part of every meal; it must largely take the place of potatoes, and wholly so that of cake, puddings, and all kinds of pastry and confections. The bread should be toasted at night, and should always be so eaten if there is much edema present. The proper way to toast bread is by first putting it in the oven and letting it dry slowly, then brown it quickly over the coals. The bread in every instance should be made of baking powder in preference to yeast.

The daily amount of food eaten should be so regulated that the same quantity will be taken at every meal. The breakfast should be at either 7 or 8 o'clock, the midday meal at 12 or 1, and the evening meal at 6 or 7 o'clock.

*Drink.*—As to the drink, many physicians say that hot water possesses most salutary properties in heart troubles, but I prefer some weak aromatic tea, as checkerberry, ginger, clove, or other aromatics of like nature; of these the patient never seems to tire. In fact I have generally found it preferred to the cup of washy, weak tea which, after having drank it strong all their life they can never be reconciled to have diluted. They prefer aromatic drinks a thousand times over, as these give them no painful contrasts of past days of freedom and unrestricted.

Let this thing be always borne in mind: the danger lies in eating too much, rather than too little, and also that wines, malt liquors, and distilled spirits are not food for the heart, and do not by their use tide over dangerous symptoms.

*Clothing.*—A few words regarding the clothing and care of the body, and then we will proceed to the medicinal treatment: in summer the patient should wear next his skin, light weight silk underclothing with light weight cotton and wool shirt over it; in winter these should be of medium weight. After

many careful observations with different textures and weights this has proved to be the best. Dressed like this the patient will seldom get cold, or be cold, or get into a perspiration.

*The Bath.*—Only warm baths should be used in cases of senile heart, and the temperature should not be high enough to heat the blood. No exact rules as to degree can be given, as the sensitiveness of the individual varies with his condition and the state of the atmosphere. Hot sponge bathing and hot shower baths are of great advantage. Hot-air baths will be found useful in many cases, but they must be of short duration and given understandingly.

*Remedies.*—The great object of the treatment is to increase the muscular power and nutrition of the heart, and give comfort to the nervous system. The drugs most potent to accomplish this are digitalis, strophanthus, convallaria, spartine sulphate, adonis vernalis, barium chlorid, nitrate of strychnin, sodii arsenias, glonoine, paraldehyde, chloralamid, chloralose, cimicifuga, collinsonia, cactus grandiflora, prunus virginia, pulsatilla, salicinum, sodii valerianas, tablets of nuclein solution, proto-nuclein powder, glycerophosphate of lime, gaffein, quebracho, kola nut, morphia, atropin, iron, copper arsenite, gold, calomel.

The earliest indication that the heart is growing old is a feeling of emptiness and uneasiness in the cardiac region of the chest, radiating around the nipple. The heart beats will be feeble, the pulse compressible. Regulate the diet and habits of the patient, remove constipation and indigestion. Give 30 grains of bicarbonate of soda one hour before meals in four ounces of water or aromatic tea. This treatment will also be aided by the following:

- R. Tr. Cimicifuga . . . . .  
Tr. Apocyni cannab . . . . . āā, ½ dr.  
Tr. Hydrastis . . . . . 1 dr.  
Tr. Zingiberis . . . . . ½ dr.  
Aqua cinnamon . . . . . 10 oz.

Mix. Give one to three teaspoonfuls after meals.

If this plan is followed out, this first downward step will be turned backward, and the patient be made comfortable, if he will obey orders. If there is indigestion, give 10 grains of peptinzyne before and after meals, with 2 grains of proto-nuclein.

If the patient comes to us with swelling of the feet, when exertion, though light, brings on dyspnea, then we must give the patient *rest*, which must be *absolute*, for a few days or even weeks. Carefully regulate his diet, and give the following:

- R. Tr. digitalis . . . . . 2 dr.  
Fluid ext. berberis aq . . . . . 1 dr.  
Tr. cimicifuga . . . . . 1 dr.  
Tr. rhamni, pursh . . . . . ½ dr.  
Tr. apocyni cannab . . . . . 1 dr.  
Aqua gaultharia . . . . . 5 dr.  
Glycerina . . . . . āā 5 dr.

Mix. Give one to two teaspoonfuls after meals, in wineglass of aromatic tea. Three grains of the iodid of strontium may be given in connection with the above. Continue this for one week or ten days, and then give the following:

- R. Strychnin nitras . . . . . 1 gr.  
Acidi nitrici . . . . . 2 drops.  
Tr. ferri chloridi . . . . . 5 drops.  
Aqua . . . . . 4 oz.

Mix. Take one teaspoonful before meals, in a wineglass of water.

- R. Fluid ext. pruni virgi . . . . . ½ oz.

Take from ten to fifteen drops after meals, in tablespoonful of water, and at the same time, five drops of liq. sodii arsenitis.

In attacks of angina, nitro-glycerin is of great ben-

efit; one one-hundredth grain tablet three or four times a day will quickly relieve the pain. In some cases the patient will require an active cholagogue purge; the following is an ideal one:

- R. Podophyllin, res . . . . . 4 gr.  
Ext. rhamni pursh . . . . . 10 gr.  
Euonymi, res . . . . . 20 gr.  
Irisin, res . . . . . 5 gr.  
Ext. colocynth, comp . . . . . 10 gr.  
Ext. rhamni pursh . . . . . 10 gr.

Mix. Make twenty pills; take from one to three pills after supper, and repeat as required.

We often have to use narcotics to quiet pain and induce sleep, that

"Knits up the ravelled sleeve of care."

The following is a good model:

- R. Morphin sulph . . . . . 20 gr.  
Atropin sulph . . . . . 1 gr.  
Caffein . . . . . 1 dr.  
Sodii benzoat . . . . . 2 dr.

Mix. Divide into one hundred and twenty powders.

Give one powder once or twice during the twenty-four hours, either per mouth, rectum or hypodermically.

When there is considerable ascites, forming part of the general dropsy, it is best to aspirate, as it saves a good deal of time, most of the serum is gotten rid of, and then the remedies will act more kindly. I usually aspirate from the scrotum, and not wait for the abdomen to fill. Every ounce of serum can be drawn from the limbs in this way. In women, aspirate from the labia.

If at any time the patient should have severe dyspnea, give the fluid extract of quebracho, in doses of fifteen to thirty drops, every three or four hours in water. I have found it invaluable.

In cases of sub-acute rheumatism the following will give quick relief:

- R. Fluid ext. cimicifuga . . . . .  
" " pilocarp . . . . . } āā 5 dr.  
" " manaca . . . . .  
" " piscidia . . . . .

Mix. Give twenty drops every three hours, in a tablespoonful of water.

If the parts are painful, the following will give quick relief:

- R. Ichthyol . . . . . 1 oz.  
Aqua . . . . . 8 oz.

Mix, and apply to the parts every four hours; cover with cotton.

In cases of senile heart, when we find the patient loaded down with fat, a lax abdomen and distended intestines, the following will give good results:

- R. Rubidii iodidi . . . . . 2 dr.  
Fl. ext. adonis vernalis . . . . . 1 dr.  
" rhamni pursh . . . . .  
" euonymi atrop . . . . . } āā 1½ dr.  
" leptandra . . . . .  
Elix. simp. glycerini . . . . . āā 2 oz.

Mix. Take one-half teaspoonful before meals, and one hour after, in a wineglass of water.

The whole body should be well rubbed with the following ointment: take of equal parts of beef marrow and leaf lard, recently prepared, eight ounces, oil cinnamon, oil eucalypti, and creasoti, of each one drachm. Mix and use once a day, special attention being given to the abdomen, for at least fifteen minutes each time.

If pneumonia supervene, the following can be given:

- R. Calcii chloridi . . . . . 4 dr.  
Strychnia nitras . . . . . ½ gr.  
Tr. pulsatilla . . . . . ½ dr.  
Infusi serpentaria . . . . . 8 oz.

Mix. Give one teaspoonful every two hours, in wineglass of spearmint tea.

When we have a gouty condition existing with senile heart, I have given the following with especial benefit:

R. Auri et sodii chlo . . . . .	16 gr.
Sodii arsenias . . . . .	15 gr.
Sodii bromid . . . . .	1 oz.
Aqua . . . . .	8 oz.
Syr. simp . . . . .	8 oz.

Mix. Give from ten to thirty drops after meals, in wine-glass of water. In some cases one to two drops every two hours will do better.

The following is well adapted for nervous fluttering about the heart in nervous women:

R. Fl. ext. pulsatilla . . . . .	
" caulophylli . . . . .	
" cactus grand . . . . .	aa 1 dr.
Aqua camphora . . . . .	4 oz.

Mix. Give one teaspoonful every three hours.

For the "tobacco heart," in elderly people:

Strychnin arsenate . . . . .	1 gr.
Quinin arsenate . . . . .	2 gr.
Salicin . . . . .	1 dr.

Mix. Make sixty powders. Give one powder after meals, or half a powder every three hours for six doses, dry on the tongue. This not only tones up the heart, but destroys the appetite for tobacco.

#### DISCUSSION ON PAPERS OF DR. BABCOCK, PATTEE AND ENGLISH.

DR. ROCHESTER—As to Dr. Babcock's paper, there are one or two points upon which I wish to take issue with him in regard to the indications for digitalis. He said that in those cases he reported there were all the indications for digitalis present, and then he states there was unequal action of the two ventricles; that the action of the left was greater than the action of the right. If we find the left ventricle acting strongly, it seems to me that it is an absolute contra-indication to the use of digitalis. The subject under discussion is the matter of the use of digitalis in certain conditions of the two ventricles, and his conclusion in that case, I think, was absolutely contrary to his own reasoning.

In regard to Dr. English's paper, as to acid intoxications, there is no question in the mind of the profession, I think, that we have numerous acids produced in the body, and have acid auto-intoxication creating cardiac instability; but to attribute to that cause the sudden deaths from cardiac instability is pushing the matter too far. There are a great many things which enter into the production of a weak heart; we must take into consideration that we have toxemias of various kinds in the body when we have that condition he described, in which the excretions showed great acidity. We must not consider simply the acid alone of the toxemias present. The careful investigation of the excretions, as to amount and chemie constituents, is of more importance than the simple acidity or non-acidity, or the lessened alkalinity of the blood itself.

In regard to Dr. Pattee's paper, it seems to me that the Doctor has gone wild over the matter of medication, giving us all the possible drugs that could be used in any way in connection with the heart. It seems to me that the present trend of medical thought is to simplify our treatment, and find out the actual physiologic action of drugs before giving them. He says that stimulants are contra-indicated in almost all cases. It would seem that this is not true, as we find in the condition of age the worn-out tissues which need stimulation if stimulation is ever needed at all, and these would appear to be the very cases in which whisky should be of use. It is a mistake to consider the heart without relation to the rest of the body. We must consider the heart in relation particularly to the capillary circulation, and in that matter I think we find the key to our treatment of all these senile hearts. In the capillary circulation if we find the vessels hard and thick as they generally become in advanced years, then before giving any medicine whatever to increase the force of the heart's action, we must relieve as far as possible this contraction of the capillaries, and that can be done by various physiologic methods of procedure, by baths and by properly given friction. That, I think, is of more importance than the administration of drugs to cause sweating, such as the pilocarpin—or the use of cholagogue cathartics, etc. The main thing, it seems to me, in old people is to keep careful watch of the capillary circulation. Then if we find that

there is marked deficient action of the heart, we must pay attention to the nervous system, and in my opinion there is no drug that comes up to opium in that matter, in controlling the action of the heart and enabling the system to go on as it properly should.

DR. H. B. SEARS, of Wisconsin—I think if we could speak of conditions perhaps more than of remedies, we should be more likely to agree, as well as be more logical in our use of remedies. It seems to me that the two cases related in Dr. Babcock's paper cover the case very well, and illustrate the use of heart tonics or stimulants. In the case in which he had the bad effect from the use of digitalis he says that he treated an enlarged liver, with the accompanying condition of what we might call venous stasis or peripheral edema. I believe it is conceded to-day that heart tonics, of which perhaps digitalis may be the type, should not be given when there exists edema or ascites until the edema or ascites is first relieved by aspiration, when the heart tonics will be effectual. Tonics are also contra-indicated in high temperature. I think these points are very important. It is not that the heart tonic is at fault, but the conditions are unfavorable for its absorption and favorable working. If we have the blood vessels already pressed upon by transudation, we can not expect that the heart will recover under this unfavorable condition. If by aspiration, or perhaps by the old-fashioned bleeding—which is, however, unnecessary—we can relieve this transudation then we can, by proper measures, bring about a normal condition.

Dr. Pattee said he would aspirate the scrotum or the labia until the edema left. It seems to me that if he would give purgatives and then give his heart tonics, strychnia included, he would accomplish all that is desired.

DR. CHAPMAN, of Louisville—I was deeply interested in the paper read by Dr. English, and am also glad to find that the trend of the papers has been toward a study of auto-intoxication as a cause of disease, for it seems to me that scientific research just along this particular line will, in the near future, explain to us a number of conditions, particularly as to the etiology of disease, in which the microscope has entirely failed. Dr. English, in speaking of the instability of the heart and its relation to an acid auto-intoxication has mentioned facts in which I heartily concur. At the same time it seems to me that if he had carried his investigations a little further he might have been able to make out the particular acid and the particular disease of the heart. For instance, within the last few months I have been making some investigations as to the chemie change in the stomach as the cause of disease, particularly rheumatism. Out of twenty-five or thirty cases that I have examined carefully, in no instance have I failed to find lactic acid present in the stomach. Lactic acid, it has been known or believed for years, is the cause of rheumatism, and I am satisfied that that assertion is sufficiently established in the minds of those present here. Accepting that as a truth, I have taken twenty-five or thirty cases of rheumatism, both muscular and articular, and examined the contents of the stomach to see what acid we would find there, or whether we would in all instances find acid present. I have conducted the examinations in this way: we know that lactic acid is present while food is being digested, that is for one or two or three hours after the meal has been taken. It is then normally in the stomach. But Boaz and Ewald have proved that lactic acid is abnormally present after the third or fourth hour. I have proved by reagents, by the ferric chlorid, that lactic acid is present in these cases of rheumatism, and this leads me to the point I wish to make, that we see in all cases of rheumatism, or nearly all cases, valvular disease of the heart or endocarditis; then if lactic acid is the cause of rheumatism, this is the agent in rheumatism which causes the heart lesions.

DR. STOCKTON—I do not feel that I am called upon to enter into a discussion on this subject, but I can not allow the occasion to pass without protesting against the theory that cardiac diseases are commonly caused by the acid of the blood. Nor can I refrain from criticising the last speaker in his statement that lactic acid is found or that it has anything to do with the matter whatever. Where it does occur in very large amount you do not find heart disease nor do you find rheumatism.

DR. WEBSTER, of Chicago—I want to call attention to the points which Dr. English makes as to the danger of acids, and to the fact that he draws no distinction between vegetable acids and mineral acids. He would lead us to infer that if we give vegetable acids these increase the acid, or rather diminish the alkalescence of the blood, because we never have an acid reaction in the blood in health. If there

is any one fact that seems well established, it is that the giving of vegetable acids increases the alkalescence of the blood. There is another important point, and that is the elimination of carbon dioxid. Oxygen is necessary in the carrying on of life processes in the body, but it is just as necessary that the waste tissues should be eliminated. We know that carbon dioxid is carried away from the tissues where it is produced, to the lungs where it is eliminated as a bicarbonate of soda. I must congratulate Dr. English on calling attention to this important point, and to the part which acids play in this condition and, especially, one point that he emphasized, probably the keynote to the whole question—the fact that the blood pressure is increased by the presence of acids in the circulatory system, and the increase of peripheral resistance increases the work of the heart. Anything that increases the work of the heart must lead either to its hypertrophy or, if that work be thrust upon it suddenly it must lead to its fatigue. I do not believe that death is ever caused by auto-intoxication in an otherwise healthy heart, and I contend that there is no condition in which there is an acid state of the blood during health.

DR. ENGLISH—I thank you for the reception which you have given my paper. I would simply respond to the first speaker, that he must not imagine from the fact that I have given my views on the acidulous conditions that these are the only views that I have with regard to heart disease. Of course it may seem, when defending a cause of that kind, that this is my peculiar view, and my only one. I feel that there are a great many things in which the paper is not complete, it having been reduced from one more elaborate. If I have called the attention of some of the other minds in this ASSOCIATION to the need of investigation in this realm, I think I have done all that I could have hoped.

## LECTURES.

### LECTURES ON INTRACRANIAL SURGERY.

#### XI.—THE SURGICAL TREATMENT OF INSANITY.

BY EMORY LANPHEAR, M.D., PH.D.

ST. LOUIS, MO.

(e.) Insanity due to softening. That portion of the cortical substance most prone to embolic and thrombotic softening is that which is supplied by the parieto-sphenoidal branch of the middle cerebral, or Sylvian artery, the left being much more frequently affected than the right. That softening of the brain—even of quite limited extent—often gives rise to insanity has for many years been a well-established fact; but the proposition to trephine in such cases is, so far as I know, wholly original with me, as I can nowhere find record of cases similar to my own. By the term “softening,” I do not mean *cerebral abscess*—all surgeons would trephine for abscess if its location could be determined—nor to that condition formerly called “red softening,” which is in reality only the initial stage of a suppurative inflammation and which if not arrested leads to destruction of the nerve fibers and cells by pyogenic microorganisms; but to that condition that follows cerebral hemorrhage, embolism of some vessel beyond the circle of Willis, or sometimes thrombosis in like region. We know that soon after the injury takes place the process of softening begins and gradually advances until a group of convulsions or even a whole hemisphere becomes but a creamy mass, containing degenerated nerve cells, masses of dark granules (blood vessels in a state of fatty degeneration), remains of connective tissue, etc., but no pus; the boundaries of such areas of softening are often quite distinct from the healthy brain tissue surrounding, which has led to the erroneous opinion that the degenerated substance becomes “encysted;” this is particularly true of softening following cerebral hemorrhage. If the skull be opened in such cases

the brain and its membranes will often look swollen and feel as if there were a sac full of fluid beneath; the puncture allows the escape of the softened mass, semi-fluid in consistence, of purulent appearance, but in reality not pus. Here, one would naturally think, is a complete hemiplegia, a total aphasia, a hemianopsia, a one-sided deafness or other manifestation of an obliterative process in the brain, with softening as the pathologic condition—a state of hopelessness that should debar even the most venturesome surgeon. Perhaps so, if there be evidences of destruction of a whole hemisphere; but frequently the focus of softening is but a limited one, as in embolism of that branch of the middle cerebral which supplies the arm center and the speech area. This particular region is selected as one for illustration because it is not infrequently affected by embolic softening and because its contiguity to the frontal gyri often causes symptoms of mental irritation; though we often see patients affected by hemiplegia without aphasia, due to either embolism, hemorrhage or thrombosis, presenting evidences of profound irritation or disturbance in those convolutions which preside over the intellect, long after the subsidence of immediate pressure symptoms.

Every physician can call to mind, patients whose characteristics were irritability, irascibility, fits of mental aberration and even homicidal and suicidal impulses, of whom he has said to friends: “You must bear with this man as well as you can as he is not responsible—he has softening of the brain and nothing can be done for him.” In former years I made this assertion many times, but now I am not so positive; in fact, I am convinced that many such cases are amenable to surgical treatment; not, indeed, as an operation to be made with the object of improving a paralysis or other manifestation of destruction of the cortex or communicating fibers, but of clearing out a quantity of irritating material and substituting one (like the blood serum or cerebrospinal fluid) which will within a brief period fill the cavity and will not give rise to symptoms of irritation.

The technique I have followed is this: the scalp having been properly cleaned and protected, a large flap of scalp and periosteum is turned back and a button removed at the point indicated by cerebral localization or otherwise. When the dura is exposed it is palpated; if indications of softening are not now present, the bone can be replaced and the scalp closed—no harm being done. If there be sufficient evidence of softening, another button is removed and the two openings joined, or the trephine hole is enlarged with forceps; when large enough to allow the underlying structures to be manipulated with ease the dura is cut with a good flap. Inspection proving the correctness of the diagnosis, a free incision is made through the pia and the softened brain tissue allowed to pour out. The cavity is irrigated with hot salt solution (temperature about 105 degrees F.) and left full of the same while the dura is closed with fine interrupted catgut stitches and the scalp sewed with a continuous catgut suture. No drainage is used and a firm compress of bichlorid gauze is applied with proper dressings. That such an operation is wholly practicable and may lead to improvement I have positively demonstrated. As an illustration the following case is cited:

*Insanity from Softening of the Brain—Operation—Complete*

*Relief.*—A. M., of Derby, Kan., age 56; had cerebral hemorrhage six years before my examination, involving speech center and area. At first he was completely hemiplegic and totally unconscious. After a few days consciousness gradually returned and later on the use of the leg was restored. At the time of examination the following note was made: "Aphasia is total, *i. e.*, practically so, his vocabulary being limited to 'You do, you do,' for yes, or acquiescence, and 'Um-um,' for no, or negation. Agraphia is total, but he recognizes some written or printed words which have been read and explained to him many times. His memory is fully as good as before the 'stroke,' but his intellect appears somewhat affected. Paralysis of right arm is complete, but a fair use of leg has been acquired. At times he is very irritable and has repeatedly threatened the life of his wife; for this, subsequently, he indicates that he is very penitent, and intimates that the impulse is beyond his control; in his sane moments he answers yes, very vigorously when asked if he regrets his mental irritability and moral irresponsibility; he complains of a band-like sensation around his head and often suffers intensely from headaches." Upon examination I made a diagnosis of softening of the brain involving the region of the lower part of the Rolandic fissure and possibly also a part of the sphenotemporal lobe as well as some of the parietal convolutions. I explained to him and to his doctors that no one beside myself had ever made the proposal to operate for cerebral softening, pure and simple, and that it was purely experimental, as well as not wholly without danger. The reply was that any danger would be encountered for a bare possibility of even incomplete relief from the fearful maddening sensations in the head.

Under such circumstances on June 27, 1892, assisted by Drs. J. F. Binnie and J. D. Griffith, I removed a considerable portion of the skull over the affected region. On turning back the dura there was disclosed a cloudy infiltrate in the pia and an apparent fluidity beneath. Taking sharp-pointed scissors I plunged them into the middle of what should have been the third frontal convolution, and withdrew them, open. There followed a gush of broken-down brain and other *débris* of creamy consistency to the amount of fully a pint; but no pus. The large cavity was carefully washed out with sterilized salt solution (*no antiseptic solution ever being permissible inside the skull*, except possibly in cases of abscesses) left filled as nearly full as possible with the fluid, the dura was replaced and stitched, and the scalp sewed into place without drainage, after careful arrest of all bleeding, and a firm compress of bichlorid gauze applied. The operation lasted but a few minutes, and the patient was put to bed without shock. He slept better that night than for months, awakening the next morning with the smiling indication that his head was better. There was a rise in his temperature to  $99\frac{3}{4}$  on the second day when he insisted upon sitting up in a rocking chair. On the third day he was up, around the halls of the hospital with a profoundly cheerful "You do, you do," in reply to inquiries if he felt better.

The improvement was not temporary, as was predicted by some who heard for the first time my proposition that such cases can be relieved by operation. He was discharged on the fourteenth day in excellent condition mentally and physically.

To this day he has had no recurrence of the bad symptoms, is passing an enjoyable life in traveling, and has sent me, I believe, six other cases for trephining; and with his grateful "You do, you do" is spreading the good news that for such hitherto helpless cases there is a possibility of relief in surgical interference. There is no improvement in his speech nor in the use of his arm, but he thinks he has far better control of the leg than before the operation.

(f). *Insanity of chronic hydrocephalus.* Chronic over-distension of the ventricles, as well as subarachnoid effusion, may end in terminal dementia. I have heard of only one operation for hydrocephalic insanity, and the result I have been unable to ascertain. It is justifiable.

3. *Epileptic Insanity.*—It is a natural and correct inference that so serious a disease as epilepsy would often lead to the development of insanity. Bucknill and Tuke calculate that epileptic insanity constitutes about 6 per cent. of all cases admitted to asylums; this does not include that very large class of cases

in which epilepsy exists merely as a complication of the mental disease. In view of the number of cases, and the frequency of operations for simple epilepsy, I am surprised that I can not find any published reports of trephining for epileptic insanity. There certainly must have been many such operations already made. I know of two cases in this city, in the practice of Dr. A. B. Shaw, the history of neither having been published. The points of interest are these:

*Epileptic Insanity—Operation—Some Improvement.*—Mr. —, who had been epileptic for many years, was suddenly seized with furor epilepticus. He was violently insane and at the end of ten days manifested no sign of improvement. He was therefore trephined upon both sides of the head. The skull was very thick and eburnated—fully one-third of an inch and like ivory, but there was no increased vascularity of the diploë as is so often met in general paresis. An opening,  $2\frac{1}{2}$  by  $2\frac{1}{2}$  inches, was made upon either side and the dura freely opened. It was exceedingly thick. No abnormal condition of the cortex of the motor region was discoverable. Upon his recovery from the anesthetic it was found that the insanity was gone. He had no recollection of any event which transpired during the ten days of his maniacal state. The epilepsy vastly improved for a long time and he was in good mental condition, but the openings finally became filled with firm, unyielding, fibrous tissue, after which the epilepsy gradually grew worse, then epileptic insanity developed and he was sent to the insane asylum where he now is; a second operation being refused.

*Epileptic Insanity—Operation—Change of Form of Insanity the only Result.*—Miss —, age 32 years, developed epilepsy at puberty. The general health became impaired, the epileptic paroxysms assumed a very severe character and at about 30 led to the development of chronic delusional insanity. The same operation was performed as in the case just mentioned. She seemed much better for a time and the epilepsy was entirely relieved for eight months. Then the convulsions became bad again, delusions once more were established with marked prominence and the insanity was fully as bad, if not worse, than before the operation. The only change which occurred was in the form of the insanity—she had a severe grade of melancholia taking the place of simple delusional insanity.

The effect of the operation in this case was much like that of my second illustration of the traumatic variety, from dementia to melancholia. While these cases do not count for much in the way of encouragement, I still feel like advising experimental trephining in every case of epileptic insanity where there is any localizing symptom; and I am not sure but Shaw is right in making double windows in the skull over the motor region in cases presenting no localizing signs.

4. *General Paresis.*—In general paralysis of the insane we have far more numerous reports than in any other form of mental disease. It is in the first stage of this malady, if at all, that I shall look for beneficial results, for here we have a mental disease (so-called) which is dependent upon gross lesion, generally slight in extent at the outset. According to Maudesley, morbid adhesions of inflammatory origin, slowly spreading, between the cortex and its investing membranes, constitute the most characteristic lesions, being absent in only a small percentage of cases. If then, by surgical means, we can arrest the spread of the trouble while it still involves that part of the brain which presides over the higher mental powers and ethical feelings—the centers which first fail almost uniformly—we may prevent implication of the motor, sensory, trophic and vasomotor regions. Upon this argument numerous operations have been made and excellent results have been recorded, notwithstanding the teaching we have been wont to accept, *viz.*, that the pathologic changes are

not purely cortical, superficial, but involve cells, vessels, fibers, neuroglia, and the ependyma of the ventricles; and that the degenerative process sometimes begins in the spinal cord. But we are compelled to accept clinical results regardless of our ideas of pathology—"conditions, not theories, confront us."

Claye Shaw has reported two cases of unquestioned general paralysis trephined at the Bamstead Asylum, in which the adhesions were broken up, iodoform dusted in freely and great improvement obtained. Another case was operated on at the Brockwood Asylum with the result that "there was marked relief of several prominent symptoms." (*British Medical Journal*, September, 1891.) Rey records a case (*Le Progrès Médical*, Aug. 15, 1891), which was able to return home in six weeks and afterward remained calm and quiet instead of the opposite conditions, which were pronounced prior to operation. The subsequent history is unknown.

One operation for general paresis was made by Wagner at the Utica Asylum. Much fluid escaped from the sub-arachnoidean space, estimated at six ounces, and a number of adhesions were relieved. There was great improvement but the patient died in six weeks. The autopsy showed pachymeningitis interna chronica hemorrhagica with cerebral atrophy. Quite a large number of other operations have been recently published—nearly all with encouraging results.

5. *Syphilitic Insanity*.—This form of insanity may depend upon minute structural changes in the brain and meninges which can not, says Fournier, be distinguished from the lesions of diffuse, interstitial meningo-encephalitis; but much more often it is caused by gumma or gummatus infiltration (the disseminated miliary nodules of Engelstadt and Lancereaux). Gummata are most frequently situated in the dura and subarachnoidean space as: 1, somewhat hard, dry, white circumscribed tumors; and 2, grayish-red, moist, gelatinous, semi-transparent masses. Manifestly some of them can be readily removed by the knife; and as internal medication only palliates—rarely cures—such cases are typically of a surgical character. I have already detailed one successful operation for syphilitic intracranial growth characterized by insane symptoms. There can be no doubt about the propriety of operation whenever there is any certainty as to the location of the irritating deposit. And even if no marked local disease be found there may be decided improvement following operation—though just *why* the change occurs I can not explain. Through the kindness of Dr. William Fuller, of Grand Rapids, Mich., I am enabled to present this history of such a case:

*Syphilitic Insanity—Operation—Improvement but not Cure—No Lesion Found*.—The patient was a man of 30 years of age, who was insane for seven years; the disease was unquestionably of syphilitic origin, but he had been flooded with mercury and iodid of potassium without benefit. The most violent epileptic seizures were of frequent occurrence. His mental condition was one of almost total wreck; his mental reflexes were nearly perfect but disconnected—he could entertain but one idea at a time. For example, when his mother visited him after a separation of three months he greeted her as if he had parted from her but an hour before; while talking with her the dinner bell rang, when he at once left her and walked to his meal and did not remember to return. He was never vicious, nor showed any evidence of interest in surrounding things or persons—he was perfectly apathetic. Examination showed marked asymmetry of the head; the right parietal eminence looked like a saucer and careful investigation showed this want of symmetry to be acquired, not congenital. From this aspect it was presumed that some

motor disturbance would be found upon the left side of the body, but this was not the case. The right side of the body was somewhat atrophied, and much weakened in its muscular contractility; the epileptic seizures were at first confined to the right side, and after they developed into general convulsive epilepsy the spasms invariably began in the right side. The right pupil was permanently dilated but was still sensitive to light. There was some incoördination. Although the external indications pointed to trouble upon the right side of the head, the localizing symptoms positively indicated the left hemisphere as the seat of irritation and at the operation these, instead of the local signs were followed. The greater portion of the left parietal bone was removed; the bone varied greatly in thickness at various points, being more than a half inch thick at the Rolandic region. The dura was not affected and the subjacent brain appeared normal. There was considerable enlargement of the Pacchionian bodies.

There was little shock from the chloroform or operation. Two hours afterward he awakened, and asked: "Has my wife gone home?" a moment later: "Has mother gone, too?" and a little later: "Did they go together?"—three questions connected with each other, in logical sequence, something unknown in the history of his disease. He improved rapidly, so that in two weeks he went all about the city with his nurse, paying carfare correctly, obtaining proper transfers, making purchases, introducing friends to each other, etc. The change was marked and gratifying. Several weeks after the operation he again became subject to epilepsy—having many severe convulsions close together; he finally sank into a comatose condition and appeared to be dying. Dr. Fuller was called and found the patient profoundly unconscious, pulse almost imperceptible, the respirations about eight to the minute, the face cyanotic and the general appearance that of a man in *articulo mortis*. The opening in the skull was greatly elevated and tense beneath the scalp instead of being depressed and pulsating. He therefore thrust a bistoury through the scalp and dura just as one would lance an abscess. Several ounces of serum escaped and two or three ounces of blood from a cut vessel in the meninges. This was caught and an antiseptic dressing applied. The cyanosis and other bad symptoms immediately subsided and in a short time the patient was up as if nothing had occurred. He soon after developed suicidal impulses and was sent back to the Michigan Asylum, where he died nine months after the operation in the post-epileptic stage of a severe convulsion. No autopsy was permitted as the asylum physician characterized the operation as a gross outrage, in spite of the marked improvement!

Had an operation been performed upon the right side of the head, subsequent to the one upon the left, the probabilities are that cure might have resulted. It is certain that operative treatment is the only one which promises much in syphilitic insanities. As I said in speaking of intracranial gummy tumors, we are puzzled at the inefficacy of internal medication; the symptoms occasionally yield temporarily to our remedies but return again and again. The conclusion at which I have arrived from a study of quite a large number of cases of cerebral syphilis is similar to that of Mr. Horsley, viz., the only hope of permanent relief lies in removal of the affected area whenever it is accessible; nor is it absolutely necessary that any lesion be found in order to effect a cure, as sometimes the insanity yields to simple craniotomy. Whether or not such a result is due to the curative action of the operation *per se*, as claimed by J. William White, matters little so long as the mental trouble is cured.

6. *Paranoia*.—Burckhardt has detailed six cases of this form of insanity with marked hallucinations, which he subjected to operative treatment. In the two cases he aimed to intersect the paths of association, which he thinks transmits the pathologic impressions coming from sensory parts and certain ideogenic areas of the brain; a portion of the frontal and parietal lobes, before and behind the ascending convolutions were removed with very satisfactory results in one case,

the other dying from convulsions on the sixth day. In three other cases the hallucinations were more or less acute and in these the operator attacked the centers through whose injury sensory and motor aphasia are produced, and removed a part of the first temporal and the third frontal convolutions on the left side, which appeared diseased, and with satisfactory results. In one patient, ablation of portions of the right superior parietal convolution and the supra-marginal gyrus caused paralysis of the left arm for seven weeks and transitory paresis of the left leg. Recovery from the paranoia was perfect. From these experiments it seems possible that with additional experience and a minute study of the pathologic changes seen in the brain, the knife may be the means of restoring to reason many cases now considered incurable.

#### RULES FOR TREPHINING FOR INSANITY.

1. Every depressed fracture of the skull should be subjected to operation at the time of accident, regardless of the amount of depression and irrespective of pressure symptoms.
2. Every case of prolonged unconsciousness following a blow in the frontal region should be trephined for exploratory purposes; upon both sides if necessary.
3. The skull should be opened in all cases of insanity dependent upon trauma, at the earliest possible moment after development of the mental symptoms.
4. Operation is justifiable in every case of serious suspicion of tumor, abscess or softening of the frontal (or any other accessible) region.
5. Operation is advisable in every insanity following cerebral or meningeal hemorrhage in which localization is possible, the clot accessible and the mental trouble of recent development.
6. Every case of insanity developing in the history of otitis media suppurativa deserves immediate exposure of the favorite site of cerebral abscess.
7. Trephining for the purpose of breaking up adhesions of an old meningitis has been successfully practiced though it is not to be strongly advised.
8. Establishment of permanent drainage beneath the scalp is permissible in the beginning of a terminal dementia succeeding chronic hydrocephalus.
9. Operation for epileptic insanity is advisable whenever there are symptoms pointing to a focal lesion.
10. Experimental trephining in the early stage of general paralysis of the insane is considered worthy of further trial.
11. Operation should be done for even a suspicion of the existence of a gummy deposit in the bone or meninges.
12. The formation of fenestræ in the skull is permissible whenever there is evidence of intracranial pressure, even of unknown origin.

## SOCIETY PROCEEDINGS.

### Association of Military Surgeons of the United States.

[Special correspondence of the JOURNAL.]

*Fifth Annual Session, at Buffalo, N. Y., May 20-23, 1895.*

The meeting this year was in every respect an unqualified success, to which the lavish entertainments of the citizens of Buffalo greatly contributed. In a professional paper like the JOURNAL, these should be passed over with a few words,

but at least an enumeration of them will be permitted as a slight commemoration of the successful efforts on the part of Buffalo.

A *conversazione* of the Microscopical Society, a similar entertainment at the Iroquois Hotel, a magnificent full dress reception at the Buffalo Club, a carriage drive to Fort Porter and other points of interest in the city, a promenade concert, review and parade, tendered by the Colonel and officers of the 65th Regiment N. G., N. Y., and a well-planned excursion to Niagara Falls with a visit to the electric power plant, composed the official program of festivities, which were interlarded with private dinner parties and luncheons, notably those given by Professor Park and Dr. Chauncey Pelton Smith.

These entertainments induced a closer acquaintance among the medical officers present and aided greatly in the harmony of the meeting. The sessions were opened at the Star Theater with a prayer by Rev. William C. Wilber, followed by Hon. Herman T. Rogers, who welcomed the visiting surgeons, on behalf of Governor Morton, to the State of New York. He was succeeded by Hon. Edgar B. Jewett, the Mayor of Buffalo, who spoke for the city of Buffalo, and then by Prof. Roswell Park, President of the State Medical Association. The latter gave a very interesting historical review of the status of the military surgeon. Col. Geo. C. Fox then welcomed the Association on the part of the National Guard, and eulogized the efficiency and progressive spirit of its surgeons. Announcements were then made on behalf of the Buffalo Committee of Arrangements by Major Albert H. Briggs, Chairman. (It may be proper at this stage of my report to speak of the very successful administrative labor of Dr. Briggs, as the elaborate program of the committee did not fail to connect in every detail.)

General George M. Sternberg, Surgeon-General U. S. Army, and President of the Association, then delivered the annual address. While giving credit to the superior facilities of civilian surgeons for gathering experience, he laid stress upon the necessity of special training for the military service. If more of this had existed at the outset of the War of the Rebellion, a great number of lives, sacrificed not only through wounds, but by disease, might have been spared. He illustrated from his experience at Bull Run, what unfortunate conditions resulted from the want of organization. Very little surgery can be done at the fighting line, and a well-trained corps of sanitary soldiers will in future wars greatly facilitate the immediate care of the wounded.

He then enumerated the changes which will take place in military surgery owing to improvements in firearms, small arms as well as artillery, and gave a description of the Hebler tubular bullet, the very latest projectile devised to still more reduce the weight of ammunition and increase the flatness of the trajectory.

The address was replete with practical instruction and it is to be regretted that no more space can be given it here.

The meeting then adjourned to the amphitheater of the University of Buffalo, where thereafter the sessions were held.

The first paper on the program was

#### CONSERVATIVE SURGERY UPON THE BATTLE-FIELD,

by NICHOLAS SENN, Surgeon-General, N. G., Ill. It was so full of practical advice that it will be difficult to give a synopsis of it, and be just to the great amount of well-digested information. The following are the main points: military surgery will no longer countenance mutilating operations except when nutrition of the limb is arrested by the injury. Prompt aid on the battle-field is first to be aimed at, and only to be obtained by a well-trained hospital corps. This embraces the treatment of hemorrhage, to counteract shock, primary dressing, immobilization and transportation. As to hemorrhage ligation can not be relied on. The best measures are elevation of limb, digital compression, forced flexion with fixation, elastic constriction (with regard to the latter it has been found that it can be borne for from four to six hours without danger of gangrene or paralysis), antiseptic tamponade. In hemorrhage of the three cavities the great triumphs of antiseptic surgery can be achieved. Favor the escape of blood from the brain by antiseptic drainage. In penetrating wounds of the chest, pack the orifice with an antiseptic tampon and secure immobility by gunstraps or other means at hand. The same means should be employed in abdominal wounds, adding to them compression of the aorta, if the injury appears below the bifurcation; direct compression in the direction of the track of the bullet. Where possible, seize

the bleeding vessel with hemostatic forceps, leaving them temporarily in the wound if necessary. Ligation will usually not be done on the battle-field. Silk is a much safer material than catgut. The ligature should not be tight enough to rupture any of the coats of the vessel. Veins should be sutured in incomplete wounds, in the same manner as Lembert's suture. Hot water will seal smaller vessels. Styptics should be condemned. Infusion may become necessary and the 6 per cent. salt solution, about 1,000 grams, is safest. Auto-transfusion by ligation after elevation may be necessary. As to shock, its effects are felt immediately after injury, while in hemorrhage the intensity of the symptoms increases progressively. Inhalation of nitrite of amyl and hypodermic injections of strychnia, one-fifteenth to one-twentieth grain, repeated are the best treatment with alcoholic or diffusible stimulants and recumbent position. The primary dressing should consist of the antiseptic package to be carried by each soldier. The best place for this is sewed inside of the cartridge belt; half an ounce of salicylated cotton, embedded in it two grams of boric acid and half a gram salicylic acid with a triangular gauze bandage. The immobilization should rely on extemporized aid, fastening sleeve to the coat, supporting the arm by lapel pinned up, rifle, saber, bayonet splints.

Improved methods of transportation are necessary, owing to increased distance of dressing station and hospital from firing line.

At the field hospital, the hemostasis will be made permanent, abdominal and cranial cavity opened if necessary. Probing is discontinued. If a bullet probe is to be used, it should be as nearly as possible the same caliber as the projectile. Craniectomy is indicated in every case of penetrating wound of the cranium. Laparotomy is advisable and feasible in penetrating wounds. Primary amputation is only justifiable by extensive injuries of the soft parts and fractures and joint wounds complicated by injury of large vessels and nerves. Primary resections for gunshot wounds of joints are obsolete. The main object will be to prevent complications by disinfection, removal of bullet, if in close proximity of joint, gauze drainage and immobilization.

The second paper, although read first, was "Asepsis in Military Service," by EDWARD BOECKMAN, Assistant Surgeon-General, N. G., Minn. He explained the best and most convenient methods of aseptic surgery, exhibiting his portable sterilizer and aseptic dressings.

The next paper, "Septic Bullets and Septic Powder," by CAPT. LOUIS LA GARDE, Assistant Surgeon U. S. Army. He related experiments in addition to those reported heretofore in Vol. LVI of the *New York Medical Journal*, showing that bullets can carry disease germs. He also demonstrated that of the various kinds of powder used, the black powder, being only consumed to the extent of 57 per cent., if fired close enough, might carry microorganisms, and may explain infections like tetanus and malignant edema in a fair proportion of the cases, while the Peyton smokeless powder contains a substance which inhibits the growth of bacteria of less resistant forms of germ life.

The next paper was on the

#### LOCATION AND DETECTION OF MISSILES,

by PROF. ROSWELL PARK of the University of Buffalo, late Brigade-Surgeon N. G., N. Y. After a historical review of the question, he announced as a main topic: 1, under what circumstances is a gunshot wound to be interfered with for the removal of missiles; and 2, how are said missiles to be treated or detected? The answer to the first query is that bullets are to be removed when they do actual harm or for cosmetic effects. The injury due to the presence of a bullet may be ascertained either by the rational or the mechanical method. The former embraces a study of the physical signs—pain, loss of function or sensation, from simple anesthesia to motor paralysis, ecchymoses, the so-called local stupor, the amount and character of hemorrhage.

The mechanical means embrace the various probes used for locating bullets. They should seldom be resorted to, owing to disturbance of blood clot, entrance of air or infection. If probing is resorted to the surgeon should be prepared to complete the work of removal at once. He then successively enumerated and explained the advantages of Nélaton's porcelain-head probe, Culbertson's meerscham-head, Deneux's method, Bauden's tire-fonds, Loulaut's trocar, Baudry's tenaculum probe, Neudörfer's saw-tooth probe; then the various electric probes (Favre, Neudörfer, Rhumkorff, Luini, Sesemann, Liebreich, Maschek, Kovars, Longmore), likewise Fenger's endoscopic method. The latest instruments are those of Professor Hughes, the induction bal-

ance, which failed in President Garfield's case, and the Girdner telephonic probe. Professor Park illustrated the action of the latter on a chloroformed dog, into which for experiment's sake shot was introduced through a trocar.

A paper by CAPT. LA GARDE, "Experiments illustrating the Degree of Powder Burn," is valuable chiefly from a medico-legal standpoint, as it demonstrated that black powder causes powder burn at fifteen feet from a long barrel, from a short one at thirteen feet, at a somewhat lesser distance with the Walsrode and American wood smokeless powder, while it is practically absent in the Peyton powder, which is used in the new U. S. Krag-Jørgensen rifle.

GENERAL J. D. GAFFITH, ex-Surgeon-General, N. G., Mo., read a paper on "Some of the Effects of the New Bullet, and how can a Soldier Protect himself?" The following are his conclusions, which generally agree with the observations of other experimenters: battles of the future will not be fought at artilleristic range; any soldier can protect himself by the use of his bayonet as a pick; the best protection is loose dry earth, the next best loose sand; at distances up to 1,000 yards the explosive quality of the missile is terrific; this explosive quality is most marked in soft tissues and cavities—the brain and lung tissues are terribly torn and the heart burst; when a viscus is grazed by a bullet, it is much mutilated; vessels are cut, not torn, hence death rate on the field will be very great (four killed to one wounded probably); tendons seem to be the only parts of the body turned aside by the bullet.

"The Value of Bromin in Military Surgery," was reviewed in the paper of M. O. TERRY, Surgeon-General N. G., N. Y. After an extended pharmacologic and historic review, he proceeded to submit his observations on this remedy and extolled its remarkable effects in dissecting wounds or cuts of all sorts by poisoned instruments, injuries made by a rusty nail, suppurative wounds, especially of joints with sinuses, and phlegmonous inflammations. His formula is 1 to 64 of bromin with bromid or iodid of potassium, which he uses either in full strength or diluted. He claimed particularly favorable results in phlegmonous erysipelas with 1 to 240, locally applied. In diphtheria he uses Testé's treatment of internal administration of 1 to 3 drops of 1 per cent. solution hourly. In preparation for operations a "weak" solution with carbonate or bicarbonate of soda. In all septic conditions 1 to 3 drops of the 1 to 64 solution every three to six hours.

LEWIS BALCH, Major and Surgeon, N. G., N. Y., read a paper on "Details regarding the Medical Service of the National Guard of the State of New York during the Buffalo Strikes of 1892," an eminently practical paper showing that the surgeons of the National Guard had been benefited by the examinations for the service, by the instruction received at Peekskill, and by the organizing talent of General Josiah Porter, and Surgeon-General Bryant. The sanitary service seems to have been well performed and considerable ingenuity shown in improvisation.

MAJOR C. CHASE WILEY, Major and Surgeon, 18th Reg. Inf., N. G., Pa., read a paper on "Field Hospital Service of the National Guard of Pennsylvania," at the twenty-eighth National Encampment of the Grand Army of the Republic, at Pittsburg, Pa., of which he was Medical Director. He equipped seventeen field hospitals and treated therein 763 soldiers and visitors, the total number of visitors being 250,000. Four hundred civilian surgeons attended this vast crowd. The territory covered by these arrangements was embraced in a circumference of fifty miles. Along the line of march, hospital tents were pitched at intervals of a third of a mile, with ambulances interspersed in the column.

The report of the Committee on Litter, nominated at the fourth annual session, was submitted by Medical Director A. L. GIBON, U. S. Navy. This committee was appointed to report a desirable form of military litter, and to solicit from medical officers plans and models. In response eleven different kinds of litters were submitted in addition to the six of the last session. The committee, whose members reside in Boston, New York and Washington, could not meet to submit the specimens to experimental trials, and therefore did not feel justified in discussing the subject in their report; they suggested that the Surgeons-General of the Army and Navy be requested to convene a joint board of medical officers of the two services for exhaustive tests, and that their decision be submitted to the Surgeons-General of the National Guard, in order that an apparatus for general use throughout the entire country may be selected. On motion, this suggestion was adopted.

An extract from the report of the committee on the organization of the American branch of the Red Cross Association, and its status in connection with the medical depart-

ment of the National Guard and U. S. Army, will show the views of this committee. In substance they report as follows: it would be unwise to place reliance on volunteer civilian aid in the important and dangerous service of the field ambulances. Enthusiasm will sustain individual volunteers in times of danger, but it can not be trusted to carry on the coöperative work of an ambulance service. Men trained and disciplined under the iron hand of military control are the only fit instruments for such work. In well-disciplined military commands the potential energy of the company is infinitely stronger than the mere sum of the powers of its individual components. Military cohesion gives increased courage and coolness to the individual and keeps the command at its post of duty, notwithstanding exposures and losses that would demoralize men having no military training. A company of volunteer civilians is liable to become disintegrated by any unexpected event of an alarming or threatening character, and such events are of common occurrence on the field of battle. . . . But although it is not likely that the American Red Cross Association will be of material service on future battle-fields, the history of the German Association and of our own Sanitary Commission shows that it may be of inestimable value in adding to the comfort of sick and wounded soldiers in hospitals removed from the actual theater of war. Besides, under the "American Amendment" the Association has grand opportunities for administering material relief in times of pestilence, famine, flood or other calamities, as the Michigan forest fires of 1881; the South Carolina earthquakes of 1886 and the tidal wave of 1893; the Texas drought of 1886; the cyclones and floods in Mississippi and Illinois.

A paper on the "Post Exchange from a Medical Standpoint" was prepared and read by MAJOR PHILIP F. HARVEY, Surgeon U. S. A., at the invitation of the Literary Committee. It excited universal interest and was an able, impassionate defense of one of the innovations in the Army for the purpose of decreasing drunkenness, increasing the comfort and contentment of the enlisted men and securing them a fair return for their money as against the extortions of the old tradership system. A careful historical review of the birth and growth of the exchange system under Government surveillance formed the first part of the paper. Testimony from a number of medical officers of the Army proving the beneficial effects on health and morality is quoted profusely, showing an almost entire disappearance of delirium tremens from the service and great reduction in minor crimes and delinquencies. Dr. Harvey in a long argument ably meets the objections of temperance advocates to the sale of light beer in the Exchange. There is an innate craving for a stimulant among all the nations of the earth. We deplore it and bend our energies to overcome it. We would, if we could, banish it with the wave of a magician's wand, but any nineteenth century child knows the impotence of such an expedient. If we can succeed in substituting a comparatively harmless beverage for one that inflames the passions, poisons the blood, and creates criminals and imbeciles, have we not partially solved the problem? It is a matter of common observation that the effects of beer upon the organism are very different from those of distilled liquors, both as they affect the intellectual faculties and the cellular elements. The lunch counter of the Exchange appears also to have its enemies, and Dr. Harvey goes to great length to show that there can be no possible harm in having the ration supplemented by a cheap lunch at the Exchange. He remarks upon the impediments to a perfect operation of the Exchange, viz., imperfect facilities and faulty arrangements, which with Government aid, which is due to an institution under its control, can be easily remedied. The destiny of the Post Exchange in the event of war is an interesting medico-military problem, which offers few difficulties to solve. He concludes by enumerating what we should try to realize in future from the Post Exchange.

COL. DALLAS BACHE, Assistant Surgeon-General U. S. A., read a paper on

#### MEDICAL FIELD SERVICE.

In future wars, he said, we will not be able to count on the litter-bearers, nor can we think of carrying away the wounded *during* the battle; the evacuation of the field in twenty-four hours is all we can hope for. (Billroth, Bardleben.) This will be due to the extension of the zone of effective infantry fire from 600 to 1,800 yards and that of the artillery to two and one-half miles with shrapnel. The percentage of wounded based on former wars can not be relied on; it will especially vary in certain parts of the field, and the medical service can neither be shifted *in extenso* nor pro-

vided for beforehand. He then gave statistics of the percentage of losses in the last few wars, which varied according to the particular conflict. While it averaged about 14 per cent., it rose in the 1st Minnesota at Gettysburg to 82 per cent., and at Gravelotte in the 3d Westphalian Regiment to 37 per cent.

The proportion of wounded to killed is generally accepted as 4 to 1, while if we accept the results of the Chilean war for the new weapons, it will be four killed to one wounded. The whole loss in battle will be increased and provision for 20 per cent. will not be excessive.

The work of gathering the wounded is assigned in all modern armies to the stretcher bearers of the line. This is a fundamental error. These men are trained as fighting soldiers and to divert them to another purpose is illogical and impracticable in the stress of an ordinary campaign. The training of these men will become unavailing too, as owing to the casualties of the campaign extensive changes will take place among them.

These company bearers are useful in garrison and encampment or after a serious battle, but should not be computed as the allowance of *personnel* for field service. Computing carefully everything bearing upon the question, distance of transport, field hospitals, reserves, casualties, the number of the medical service should be 4 per cent. of the force.

We are without a general scheme of arrangement and finished detail, outside of the management of our posts. The organization of our Hospital Corps is suited to a highly divisible administration, that of garrison or post service, but there is no compact cohesion—the men are not a disciplined body. The present division of line of assistance between the troops engaged and the division hospital is the collecting station, 800 to 1000 yards from the line. This is attended to by the company bearers at present, which, as mentioned above, would not be feasible at all times in actual war. This calls for a high degree of military training on the part of medical officers.

The next paper was by LIEUTENANT LINCOLN CHASE, Mass. Vol. Militia, on the "Measures for Prevention and Suppression of Dangerous Diseases in Garrison and in the Field." He showed that during the late wars, from the Mexican campaign to the present time, the proportion of deaths from wounds to those from disease were from 1 to 7 up to 1 to 2, according to the duration of campaigns. Theoretically, all diseases are preventable. The prevention should begin with systematic careful recruiting, especially avoiding acceptance of very young men. Young men from the cities are preferable, unless there is time for a year's training. An efficient sanitary service will, in the field, be a great preventative. Among the special measures of prevention, after enumerating those known to every trained medical officer, he mentions bacteriologic detection of diphtheria and tuberculosis in camp, which seems scarcely feasible.

I regret, that as I am about approaching the consideration of the next paper I find that I have almost reached the limit of the space allotted me for this report, as it is worthy of a full and careful synopsis. If I dispose of it in a shorter manner, it is done with great regret, as a wide dissemination of the unusual amount of information conveyed is most desirable.

#### The paper is the second one of COL. DALLAS BACHE on the SELECTION OF SITES AND THE CONSTRUCTION OF MILITARY POSTS IN RELATION TO PROPER SANITATION.

Three considerations govern the location of every post: military necessity, convenience, and health. The latter has been least consulted. Commercial necessity in construction of cities entails military necessity in the location of works for their protection. But in the construction of our Western posts absolute location in a particular site was not necessary and if sanitary advice had been consulted, loss of life and expensive removals could have been avoided. In the location of the large permanent posts throughout the country we have reason to expect certain sanitary interrogatories and careful consideration of the replies. There is a tendency to ignore the deeper exhibits of the soil, its air, water, temperature, although they have a highly probable relation to health. The regional climatic conditions, such as direction and velocity of the winds, the amount of rain and snows, the prevalence of fogs must be considered, as well as too much or too little shelter by hills. The subjects of ground air and ground respiration are important,—an aerial tide, rising and falling with the ground water, moving readily in all directions, loaded with carbon dioxid, the deadly gas, in some places up to 80 per cent. always under the control of the ground heat. The ground water is another important

sanitary factor. The composition of the soil will teach us its absorption, and the floor of the subsoil its disposition. The diurnal and annual curves, the former reaching four feet, the latter from fifty to one hundred, are of great importance. For example, we know that a soil rich in the products of vegetable decay, freely supplied with moisture by rainfall or from the ground water, especially if the latter is stagnant and superficial, and combined with these a soil temperature of about 65 degrees F. will produce malaria. Tuberculosis, cholera, typhoid fever, diarrhea, dysentery are more or less affected by the condition of the soil. This is not new, but not generally understood. As an example he cites one of the new permanent posts, the ground water on whose site is so superficial that when the foundations were laid the pumps had to be in constant use, while a short distance off a dry ridge could have been selected.

The consideration of the water supply and the disposition of liquid waste are also subjects for consideration. One of our newer posts obtains its water from two artesian wells, and its liquid waste flows upon a sewage farm owned by private parties—a precarious arrangement.

As to the construction of posts it includes quarters for the officers, the non-commissioned staff, barracks, hospital, guardhouse, storehouses, bakery, stables, repair shops, administration building, gymnasium, riding hall and crematory. There should be a fixed amount of floor area, cubic space and rates of air renewal, based in the everlasting change of the composition of our units, on a possible maximum. The bathrooms and closets should not be distributed among the companies, but should be central, under one management, removed from the barracks. The barracks should not be in one building, but separate pavilions.

The result of more careful attention to the sanitary condition of troops is that from 19 per cent. of mortality during the period of 1840-59 it has fallen to 4 per cent., not including war losses, with a corresponding ratio for discharges for disability.

The last paper read was by MAJOR A. C. GIRARD, Surgeon U. S. A., on

DUST A SOURCE OF TYPHOID INFECTION, a histological and clinical essay, based on his experience during the Chicago riots, when a part of the cavalry, who were camped on newmade and probably infected ground, had thirty cases of typhoid fever, while Chicago was healthy, and troops camped on other ground or in the city did not suffer. A whole regiment of infantry, camped on the same ground with the above cavalry, had no cases of typhoid. The water and food was the same for all the troops. The flies were equally bad through the whole camp. By exclusion he believes this to be dust infection, from dust groomed off the horses and deposited in the mouths of the men.

A large number of other papers were presented and read by title. An enumeration would not add to the value of this report.

A pleasing incident occurred on the second day of the meeting, when Major J. V. R. Hoff, Surgeon U.S.A., on behalf of the Association, in an eloquent speech presented to Surgeon-General N. Senn, N. G., Ill., a massive silver trophy in the form of a circular shield about eighteen inches in diameter, upon which was represented a ministering angel with the recumbent figure of a wounded soldier in bas-relief; in the center the red cross in red enamel; around the outer edge of the buckler in raised letters was the following inscription: "To Nicholas Senn, M.D., Ph.D., L.L.D., Surgeon-General N. G., Ill., the Association of Military Surgeons of the United States inscribes this testimonial, in grateful recognition of his services as its founder and first President, and in the advancement of military surgery. Fifth Annual Meeting, A.D., MDCCCXCV." General Senn responded with his usual eloquence.

### Medical Society of the State of Pennsylvania.

*Proceedings of the Forty-fifth Annual Meeting held at Chambersburg, Pa., May 21, 1895.*

[Special correspondence of the JOURNAL.]

The President, DR. JOHN B. ROBERTS, of Philadelphia called the Society to order at 9 A.M. Prayer was offered by REV. J. A. CRAWFORD.

HON. J. STEWART delivered an Address of Welcome.

The Secretary read his report, showing the marked improvement in the membership of the county societies, due to the efforts of the committee on the extension of membership.

The President briefly outlined his views as to the present management of the State Society, by which the details of business are left solely in the hands of the Committee of Arrangements. He urged the reference of the work of the society to the board of trustees. On motion, a committee of five was appointed to consider this idea and report next year. Committee: Drs. W. T. Bishop, of Dauphin; Alex Craig, Lancaster; W. H. Daly, of Allegheny; H. S. McConnell, of Beaver; and on motion Dr. Roberts was made the fifth member.

Report of the Treasurer showing a large surplus in the treasury, and of the Publication Committee, showing the publication of 2,700 copies of the transactions and the mode of their distribution was read. The recommendations of the latter were referred to the special committee of five.

The Scientific Committee reported their work, the adoption of seventy-five papers for the meeting.

DR. A. KOENIG, of Allegheny read the report of the Committee on Pharmacy, giving a concise account of a number of new remedies and their value.

DR. EDWARD JACKSON of Philadelphia, read the report of the delegation to the AMERICAN MEDICAL ASSOCIATION for the meetings of 1894 and 1895. This report congratulated the society upon the expected improvement in the ASSOCIATION JOURNAL as a result of the efforts of this society.

DR. C. L. STEVENS BRADFORD read the report of the committee on extension of membership, showing the awakening of interest throughout the State in regard to county societies, a general effort to increase the membership, and a plan for the extension of university teaching by means of lectures, etc., to be given by prominent members, the traveling expenses, only, to be borne by each society. It was agreed that this work should be continued by a much smaller committee.

DR. H. G. MCCORMICK of Lycoming, read the report of the Board of Medical Examiners, showing the result of the examinations held thus far, etc.

The report of the Rush Monument Committee was read and the committee continued. DR. H. F. HANSELL of Philadelphia, read the report of the committee on contagious ophthalmia, and presented the bill now before the Legislature on this subject. A full discussion ensued, as many seemed to feel this might prove mischievous legislation. Finally the report was adopted. The action of the committee in presenting this bill was approved.

The report of the Legislative Committee relative to the efforts for a law to prevent the disclosing by physicians of communications from patients in the courts, which was defeated, and for the care of the insane, which thus far showed no results, was read and the committee continued.

The afternoon session was almost wholly given to the reading of scientific papers.

DR. I. C. GABLE of New York, read the "Address in Medicine." He gave a review of the present status of thought of the more important subjects which have excited general interest in the past year. The various morbid processes which are grouped under the class of infectious diseases received special consideration. He regarded the antitoxin blood serum treatment of diphtheria and other infections as the most important advance recently made in modern therapeutics. Modern chemistry and medical progress is rapidly enriching the materia medica in the new antiseptics and is making solid advances as to the true action of those medicines, at first employed empirically, which have long been used as disinfectants and specifics. We are largely indebted to bacteriologic science and laboratory technique for the clearer light which we possess to-day of the etiology of many diseases and the true mode of action of many medicines.

DA. T. D. DUNN of West Chester, read a paper on "Sequelæ of Typhoid Fever." Erythema nodosum occurred in three cases; arterial and venous thrombosis in two cases; abscesses and parotitis in two, nervous affections in five cases. These complications were given in full with their treatment.

VICE-PRESIDENT R. ARMSTRONG of Clinton, in the chair, the PRESIDENT DR. J. B. ROBERTS, read a paper on "Treatment of Malignant Tumors with the Toxins of Erysipelas." An account was given of the reasoning by which Coley was led to attempt the cure of inoperable malignant tumors by the toxins of erysipelas. The method of preparing the toxins and the reasons for combining them with the toxins of bacillus prodigiosus were given; the author reported three cases in which he used this method with success. He also referred to the successful cases reported by Coley and others. Stress was laid upon the fact that the only proved cure of malign-

nant disease is early and radical extirpation. The toxins may have to be used in cases that have postponed operation too long, or after the operation, in the hope that recurrence may be prevented. The hypodermic injections of the toxins are liable to be followed by depression of the patient's strength, but are justifiable because they hold out the only hope of success in cases not suitable for operation. Sarcomatous tumors were said to be more amenable to this treatment than carcinomas.

DR. JAS. TYSON of Philadelphia, read a paper on "Typhoid Fever and the Cold Bath," and exhibited an apparatus for the purpose, which was readily used with but little disturbance to the patient.

DR. J. M. BALDY of Philadelphia, read a paper on the "Prophylaxis of Pelvic Inflammations in Women." He alluded to the number of ailments which arise from these. The main, practically the only cause, the gonorrheal infections. These spread over the whole mucous surface, prevent the occurrence of the pelvic infection, and attack the acute endometritis early before it has passed up. The danger of the infection is lessened and the power to create damage in the tubal cavities is diminished. In all cases of acute gonorrhea which have extended into the uterus, the patient must be looked upon as suffering from an acute endometritis. In acute puerperal cases the germs first attack the free blood clots and accumulated exudates in the cavity of the uterus. Here the free use of the intra-uterine irrigator will flush out the infected products and end the trouble. If the patient is allowed to go for twenty-four hours, in all probability the infection has passed beyond the reach of douching. Then we must follow the germs to their hiding places. The curette now comes in and must be used thoroughly. He described the method of operating.

DR. J. M. BATTEN of Allegheny, read a paper on "Tuberculosis." He showed by clinical observation that the tuberculosis habit is visited to the third and fourth generations. That as far as it came under his observation it is not contagious. At least only slightly among those who have not inherited the tuberculous diathesis. He spoke of the cell theory of tuberculosis and the old theory of heredity, and closed by stating that the proper plan to prevent the disease is to educate the young people how they ought to select wives and husbands in order to have healthy posterity.

DR. W. S. STEWART of Philadelphia, gave his experience in the treatment of diphtheria with the subsulphate of iron. He detailed at some length his cases, insisting upon this as the plan of treatment which offered the best prospect of safety.

DR. J. W. ROOF of Harrisburg, read a paper on "Acute and Chronic Cystitis," and its successful treatment with the bichromate of potassium. He alluded to the causation by neglected gonorrhea, the unskillful use of the catheter, sepsis, etc. Remove the cause, rest in bed, keep the urine neutral, and diluted; locally washing out the bladder, then follow with astringents, etc. Boracic acid is best, hydrogen dioxide and the potassium permanganate are useful. The bichromate of potassium had in his hands been of great value, and he did not know of its use by others.

DR. H. R. WHARTON of Philadelphia, read a paper on "Treatment of Nævus." He recommended the application of nitric acid to the capillary nævus, or ethylate of sodium, but preferred the use of the nitric acid in this form of nævus. In the treatment of port wine mark, he recommended multiple scarification or electrolysis. In the treatment of venous nævus he preferred excision in favorable cases, as a treatment which was most thorough and left the least deformity. In cases unfavorable for excision by reason of their size and situation, he recommended the use of the ligature or subcutaneous ligation. He called attention to the importance of early treatment in all cases of nævus, on account of the rapidity of growth in this form of vascular tumor, and insisted upon the importance of watching these growths carefully and if they increased in size he considered it very unwise to delay the prompt resort to some of the various forms of surgical treatment.

DR. E. LAPLACE of Philadelphia, read a paper on one hundred and twenty-five cases of hernia in which the radical cure was performed. This was a detail of his cases, showing the best method for the relief of this trouble.

DR. H. S. ANDERS of Philadelphia, read a paper on

#### THE PRESENT STATUS OF THE SANITARY MOVEMENT FOR THE ADOPTION OF THE INDIVIDUAL COMMUNION CUP.

Attention is directed, at the outset, to the fact that while the possible, even the probable dangers of the communion cup were recognized, privately and several times publicly,

by the members of the medical profession, it has been but little more than one year since the first use was made of the individual communion cup by any church. This method of administering the communion wine is now believed to be the only sanitary, safe and entirely practical and successful procedure. Besides it has the sanction of scriptural precedent, and of ministerial argument and recommendation. One year's history, carefully scanned, reveals marked progress, not only in the awakening of interest and some general study of the grounds for the innovation; but also in the ready adoption of the individual cup in a rapidly growing number of churches of most Protestant denominations. It is hardly necessary before a body of intelligent and wide-awake physicians, to argue in abstract still less in detail, in favor of the change. The writer's paper, "Prophylaxis in Churches needed by the adoption of Individual Communion or Chalice Cups," read before the Philadelphia County Medical Society Sept. 26, 1894, contains the historical, rational (inductive and deductive) and practical argument for the abolition of the common and the substitution of the individual communion cup. Since the first bacteriologic investigation by Dr. Chas. Forbes (U.S.M.-H. S.) of Rochetter, N. Y., of the common cup's rim and the dregs after a communion service, and the writer's studies two months later, so many churches have obtained and used the individual cup method, that it is difficult to estimate their number.

The first church in Christendom, so far as known, to adopt this modification was the North Baptist Church of Rochester, N. Y., at the communion service held May 6, 1894. Within one month thereafter, fourteen churches in that city had made the change, and six more had signified their intention to do so. These included the Baptist, Presbyterian and Methodist denominations.

After the writer's investigations, the Fourth Baptist Church adopted and first used the individual communion cup in Philadelphia. One Presbyterian, one Methodist and one Reformed Church have followed. The Baptist, Presbyterian, and Reformed pastors are agitating the matter in their respective congregations and associations. In New York City, in Brooklyn, in Pennsylvania, Massachusetts, New Hampshire, Ohio, Illinois, Missouri, Virginia, Georgia, and California, and perhaps other States the movement is progressing after calm, intelligent and reverential thought. The State Medical Society might well sanction the wholesome sanitary reform by stamping it with its official approval and adopting suitable resolutions to be forwarded to the county societies, health boards, and church ministerial associations.

DR. J. M. BARTON, Surgeon to the Jefferson College Hospital and the Philadelphia Hospital read a paper on the

#### DIAGNOSIS AND TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

Within the last few years the public are ready to accept surgical aid with much less deliberation than formerly, but they still deliberate too long in cases of acute intestinal obstruction. Until recently the chance to operate at all, in such cases was extremely rare and unless our successes are greater than they have been there will be but little to encourage the sufferer, in future, to submit to the knife. The mortality is enormous and almost entirely due to delay before operating. If it were done early, while the patient is yet in good condition but few would perish from an abdominal section, lasting twenty minutes, and almost bloodless. Both in hospital and in private the patient is not unusually in dying condition when the operation is agreed to. The writer narrated in full one case where the patient was sent 250 miles, to him on the eighth day of the disease and the fifth of fecal vomiting; the collapse was so great that though the operation lasted only ten minutes he perished a few hours later; if the operation had been performed five days sooner, when fecal vomiting appeared, he would have recovered.

Acute obstruction is divided into four forms:

1. Strangulation by bands or through apertures; this form is most frequent in young adults with a history of previous peritonitis. Vomiting begins early and is generally stercoraceous, constipation is continuous and absolute, tenesmus is absent, there is great prostration. Such cases require immediate operation as death generally occurs by the fifth day.

2. Volvulus. Here the bowel is so tightly twisted as to at once obstruct the nervous and vascular supply and produce immediate prostration. It occurs in males over 40 who have suffered from constipation. Local tenderness occurs early, vomiting appears late and is rarely feculent; constipation is absolute.

3. Intussusception occurs mostly in children. A tender

tumor can be felt in the abdomen and occasionally in the rectum. Absolute constipation is rare; diarrhea with blood is not uncommon.

It is not well to spend valuable time in attempting to determine the character of the obstruction; it is enough to know with certainty that the intestine is obstructed and the obstruction is not due to fecal impaction.

*Diagnosis of Acute Obstruction.*—An individual, probably in perfect health, is suddenly seized with severe abdominal pain which may remit or distinctly intermit. The abdomen is not tender at first, copious and severe vomiting appear early, the matters vomited are first food, then bile, then coffee-ground looking material and lastly they are stercoraceous. Before the coffee-ground vomit appears, mouthfuls of reddish water are often brought up without nausea or retching. Except in cases of intussusception the constipation is absolute, not even wind passing. There is some abdominal distension and marked shock.

Acute obstruction must be differentiated from

1. Ordinary colic from indigestion. This is preceded by signs of indigestion; gaseous eructations accompany the vomiting, gas is freely passed by the bowel, diarrhea usually accompanies or terminates the attack; the vomiting never becomes coffee-ground or fecal.

2. In hepatic colic the pain and tenderness is at the margin of the right ribs. The pain is intense with complete intermissions, the vomiting is never feculent, there is no constipation, gas passes freely, there is no abdominal distension, light jaundice may be present and occasionally chills and fever.

3. In renal colic the pain begins over one or the other kidney, then passes down the ureter to the testicles and thighs. The urine is scanty and may contain blood; it is passed frequently and with pain; there is no constipation and no abdominal distension.

4. In appendicitis the vomiting ceases in a few hours and never becomes stercoraceous, the pain increases and is limited to the right iliac fossa. There is frequently a distinct mass, and always an exquisitely tender spot to be found in the same region; the temperature is usually elevated and constipation is unusual.

5. In general peritonitis a history of injury or preceding disease can usually be found, the bowels act freely and wind passes readily in the early stages of the disease. The vomiting is rarely violent.

Fecal impaction is most common in adult females with mental troubles; there is a history of long-continued and severe constipation, vomiting appears late, is scanty and rarely feculent. The retained feces can be felt in the colon.

*Treatment.*—The medical treatment consists in washing out the stomach, kneading the abdomen, inverting the patient and giving injections of air, gas or water. It is rarely successful, exhausts the patient, wastes valuable time and occasionally ruptures the intestine. In but few of the cases I have examined could any of these methods have produced the slightest effect. If these methods are not immediately successful, the abdomen should be at once opened and under no circumstances should operation be delayed after coffee-ground vomiting has appeared. When obstruction is suspected, all preparations should be at once made for the operation, so that the moment the diagnosis is unmistakable there may be no delay whatever; it ought to be usually done within twenty-four hours of the appearance of the symptoms. If the location of the obstruction is known the most convenient incision is made, if not known a median incision, just below the umbilicus and large enough to admit the hand is employed. If the seat of the trouble be not at once evident, the head of the colon is sought; if it be distended the obstruction is in the large intestine and is readily located. If the head of the colon be not distended, the collapsed cecum is rapidly passed through the fingers until the seat of the difficulty is arrived at. If the obstruction is due to a band it should be removed close to its attachments so that it may give no further trouble. When it is due to an adherent appendix or to Merkel's diverticulum they should be entirely removed. In strangulation through slits or apertures, it is well to close the abnormal opening after the bowel has been reduced. If the strangulated gut be gangrenous it should be removed and an artificial anus made. An anastomosis operation can be performed later if the patient survive. The patient in acute obstruction is never in a condition to have the shortest anastomosis operation performed. A volvulus must be untwisted and an intussusception reduced. If reduction is impossible, an artificial anus must be made above the obstruction. If, after we remove an obstruction, no matter what its nature, the bowel

be much over-distended, it must not be left in this condition, but must be emptied even if we have to puncture it for the purpose or establish an artificial anus. If the patient is in extreme collapse, with a rigid distended abdomen, operation should not be refused. No anesthetic should be given as it is apt to provoke fatal fecal vomiting. Heat and strychnia should be freely used. A short median incision just below the umbilicus should be made, just large enough to permit a finger to enter and bring out the first distended loop of bowel that presents itself; an artificial anus should be made and opened at once.

If the patient is to be sent to a city hospital, wash out the stomach and give stimulants, use strychnia hypodermically, put the patient on a stretcher and surround him with artificial heat. Send short plain history with him. Telegraph surgeon so that the ambulance may meet the train and there may be no delay when the patient reaches the hospital.

#### EVENING SESSION.

The President called the society to order at 8 o'clock.

DR. H. H. LONGSDORF, of Carlisle, read the Address on Hygiene. She entitled it

#### THE MORAL FACTOR IN HYGIENE.

The science of hygiene is under a great onward impulse through the discoveries and researches in bacteriology. The theories based upon these researches have seemed to make the health problem an easy one to solve, but in spite of these tangible results the retrospect and outlook are not reassuring. Many questions on sanitary lines remain unsettled and there is a growing fear that the race product is on a lower average than formerly, that the vigor and manhood which constitutes the real wealth of the nation is declining.

The causes for this must be looked for in the increase of the dissolute and defective classes and the want of restraint put upon their disease-developing power.

Hygiene in its ultimate meaning is *race development*, and from this standpoint it must be considered among the many humanitarian and sociological questions that perplex the thinker and threaten the integrity of the body politic. If prevention is the keynote of the medical thought of the day, it is the height of wisdom to pay heed to the sources of moral contamination. Overcrowding in cities, child labor, unnatural and unremitting toil by the mothers, are some of the most potential of these causes, and they appeal to the hygienist and to the legislator on the basis of race deterioration and loss to the State.

The absolutely dissolute should be isolated and their labor made productive; 1, to prevent the transmission of their pernicious qualities; 2, to relieve the State of the burden of their maintenance in asylums and reformatories.

DR. G. BETTON MASSEY, of Philadelphia, read a paper on

#### RECENT EXPERIENCE IN THE ELECTRICAL TREATMENT OF FIBROID TUMORS AND CATARRHAL AFFECTIONS OF THE UTERINE TRACT.

In the treatment of two classes of fibroid tumors there is no conflict between the claims of electricity and of the knife. There are cases in which electricity in expert hands can give 100 per cent. of practical cures, not necessarily cosmetic cures, but completely satisfactory, in the comfort and well being of the patient. There are also cases in which electricity can only do harm, and in which ablative surgery is not only wise but imperative. In a third class true conflict occurs, and I may specify this class as made up of large tumors causing much deformity, which by reason of their situation or constitution require prolonged efforts for electrical absorption. If the deformity is great it becomes a question for the patient to decide whether the danger of an operation should not be faced. Operations are frequently performed on small tumors, in which a complete and permanent cure can be assured by electricity. Hemorrhagic tumors of all sizes should be placed under treatment of this kind, the author never having had a failure in curing a hemorrhage or pain and reducing the size. Of non-hemorrhagic large tumors, reduction or disappearance is most certain in instances of symmetrically developed interstitial growths. The class in which electricity is not indicated embraces degenerating tumors, quickly growing tumors, and all tumors associated with purulent inflammation of the appendages. One of the most important services of electrotherapeutics to gynecology is the prevention and cure of tubo-ovarian disease. This affection is dependent upon a uterine catarrh, hence the cure of the endometritis is in many cases the prevention of the former. The positive pole is indicated within the uterus and the negative within the vagina at different applications. A large number of young girls have thus been restored to full womanly health in

spite of the fact that some of them had been advised to submit to an unsexing operation.

DR. C. P. NOBLE, of Philadelphia, read a paper on "Movable Kidney." He gave at length the mode of diagnosis, etc. The trouble seemed much more common than he had apprehended when he came to review the number of cases which had come to his notice.

DR. BENJAMIN LEE, of Philadelphia, read a paper on

#### THE NECESSITY FOR A STATE SYSTEM OF REGISTRATION OF VITAL STATISTICS IN PENNSYLVANIA.

It is a matter of profound astonishment to intelligent foreigners visiting this State, and even to residents of neighboring States, that the great and venerable commonwealth of Pennsylvania, while having nominally a Central Bureau of Vital Statistics and a State Superintendent of Vital Statistics, is almost alone among civilized governments in failure to furnish the machinery by which such a system can be efficiently maintained. Apart from the general advantage of such a system and the question of State pride, there is the fact that the demand for its establishment is widespread, and constantly reiterated by a large and intelligent class of our citizens for all kinds of purposes. Inquiries for such information come from professional men, manufacturers, corporations, libraries, literary societies, the various departments of municipal administration and from officials of all kinds. It may safely be said that vital statistics form the basis of all sanitary work. Their registration and tabulation are to the sanitary officer, and therefore to the State, what "taking account of stock" is to the merchant.

1. In order that municipalities may understand the necessity for sanitary work it is not enough to quote to them the statistics of foreign countries. They need to have the subject brought directly home to them, by showing that a neighboring town or village has exactly so many fewer deaths, or so many fewer hundred cases of sickness each year than take place within its own limits, from the fact that the neighboring town has spent more money to obtain pure water by an improved water supply, pure air by abating nuisances, and pure soil by a proper system of sewerage. In Massachusetts and nearly all the New England States, in New York, Michigan, Illinois and many other States of the Union, such systems have been in active operation for a considerable period, and the records have proved of the greatest value, in the direction just mentioned.

2. Registration of vital statistics has an essential use in preventing the concealment of crime. The statement will scarcely be credited that in this State outside of large cities and a certain number of incorporated boroughs, human beings may die and be put under the ground without official record of any kind of the circumstances. The death of a blooded horse or an Alderney bull is carefully registered in the Herd Book, but the man dies and leaves no trace, as far as any record for future reference is concerned. Is it any wonder that grave-yard insurance has flourished in Pennsylvania? In a civilized community no one should ever be buried without a burial certificate issued by authority of law, and a statement of the cause of death attested by a physician.

3. Properly recorded vital statistics ensure the means of proof of personal identity, of right to property, and of substantiating just claims for the pensions for widows and orphans of those who have died in the defense of their country.

4. A ready means is thus afforded of the proof of age for the prevention of election and other frauds.

5. But outside of these conditions, weighty as they are, when we regard the conditions of a State rather than a city, we have to consider those of the growth of the commonwealth and the relative increase of population. It is desirable to know how many children are born each year in the State, whether they are of native or of foreign parentage, and what the relation of the number of births is to the number of deaths, and thus be able to appreciate what is the natural movement of population, independently of increment by immigration.

6. The writer is convinced that there is no State in the Union with a lower general death rate than that of Pennsylvania, but he has no means of showing it to be so. As indicating the value which is placed upon work of this kind in other States, it may be mentioned that New York employs from six to eight clerks on Vital Statistics alone, whose salaries aggregate \$8,000; Michigan employs seven with salaries amounting to \$7,000; Massachusetts five clerks and an editor, with salaries amounting to \$4,220; and the little State of Rhode Island, whose entire population is less

than that of "Greater Pittsburg," one clerk at a salary of \$500. There is a bill now before the Legislature of Pennsylvania providing for the appointment of a clerk in the Bureau of Vital Statistics at Harrisburg, and calling for the very modest appropriation of \$5,000 to inaugurate and carry on this important work. It is hoped that this society will put on record an expression of its approval of this effort to elevate Pennsylvania to the plane of other civilized commonwealths.

DR. T. S. CULLEN, of Baltimore, Md., having been elected a member by invitation read a paper on "Carcinoma Uteri," illustrating it by an admirably prepared diagram of the uterus.

DR. G. S. HULL, of Chambersburg, read a paper entitled "Ten Minutes in Electricity." He alluded to the electrolytic effect in removing hair; the effect is obtained from eight to ten LeClanche cells connected in series. It is cheap, free from odor, and easily kept in order. It may also be used to remove warts, in uterine growths, etc. Here, is need for the skillful only to tread. Electric humbugs are abundant, as the electric inhaler, electric head band, electric hair brush, etc. He alluded to argon which he believed the polarizer causes the skin to absorb, not oxygen as thought, by many. To lie down on a downy couch when overworked or ill, and by a conductor running from an ankle to a polarizer, and with another cord leading from the instrument with its imperishable material to the moist earth or a cake of ice, to cease even from the labor of breathing, and have this perpetual source-of-energy machine force argon into one's blood and give new life to every part—"this were a consummation devoutly to be wished."

Adjourned till Wednesday.

#### SECOND DAY.

The society resumed its sessions at 9 A.M.

The Nominating Committee was announced and retired to prepare its report.

DR. C. L. STEVENS, of Athens, read the Address in Surgery. He urged the use of anesthesia as necessary for the proper doing of the work of the surgeon. Next the need of care in diagnosis, the careful attention to details, to rest in pain, to the need of massage and motion early in joint injuries, to the keeping of limbs in proper position during inflammation, lest we have ankylosis, contraction of muscles, etc. Examine with great care in all cases of pain, in the bowel lest we overlook a strangulated hernia; in all pain and swelling of joints, lest we have pus, when we are only thinking of rheumatism. Regard with much suspicion any breast trouble lest there be cancer and it get beyond the reach of our skill. He spoke of the needed care as to sepsis, and gave at some length the proper method of assuring this.

DR. F. LE MOYNE of Pittsburg, read a paper on the

#### NECESSITY FOR THE ADVERTISEMENT AND ISOLATION OF CERTAIN INFECTIOUS AND CONTAGIOUS DISEASES.

He urged upon the profession the importance of this idea especially in scarlatina and diphtheria. Such affections are conspicuous causes of suffering and mortality and by proper precautions they are to a great extent preventable. Existing laws in our State commit the strange inconsistency of exacting precautions and enforcing restrictions in regard to smallpox, which is to a great extent under control by vaccination, while scarlatina and diphtheria to which a much larger proportion of the population are susceptible, are not subject to proper legal regulations and have almost unlimited opportunities for dissemination. The members of the medical profession are the natural and acknowledged guardians of the health of the people, and it is incumbent upon them to lead the public mind safely in that direction by emphasizing the fact that every case of scarlatina or diphtheria not carefully isolated and plainly placarded is a shameful menace to the surrounding population.

DR. J. J. BUCHANAN of Pittsburg, read a paper entitled,

#### RUPTURE OF THE TENDON OF THE QUADRICEPS FEMORIS,

giving a summary of the literature of this comparatively rare accident, together with the history of a case in which he had opened the knee joint, drilled the patella and sutured the tendon in place. The result was all that could be desired, a strong and useful joint. He quoted the statistics of the injury as compiled by Maydl of Vienna, and Bull of New York, and added cases of his own collection which had been reported since the papers were published, as well as a few which had been overlooked by these authors. The total number of cases given is 120. Suture of the tendon was performed in ten cases, as follows: 1. Lister (1878) in Roxburgh's

case, by a complicated plastic operation repaired an old rupture with buried catgut sutures with a good result.

2. Luning (1880) sutured the tendon with catgut as a part of the repair of an open wound, made by a butcher's cleaver; result a freely movable joint.

3. McBurney (1885) sutured the tendon with catgut and a wire retention stitch; result perfect.

4. Wilkin (1887) sutured the tendon with silkworm gut as a part of the repair of an incised wound of the thigh, with good function and almost perfect flexion.

5. Kaufman (1888) sutured the tendon to the muscle from which it had been torn; complete recovery.

6. Midelfast (1888) operated on a case in which the patella was found driven between the femur and tibia. He sutured the tendon and secured primary union.

7. Bull (1888) sutured the tendon with catgut, with good result.

8. Chaput (1893) sutured the tendon.

9. Buchanan (1894) drilled the patella and sutured the tendon to it with silkworm gut, perfect result. Considering the fact that without operation, an imperfect result has occurred in about half of all cases, the author considers the operative procedure one to be recommended.

DR. JOS. E. WILLETTTS of Pittsburg, read a paper on "Intra-Tympanic Disease."

DR. A. P. HULL of Montgomery, read a paper on "Treatment of Typhoid Fever by Guaiacol." This was a report of thirty-two cases treated during September, October, November, December, 1894, and January, February, 1895. The first eleven with two deaths, and the last twenty-one with guaiacol internally continuously, and externally when necessary to lower the temperature, with no death; an average duration of fever of nineteen days, with the grave symptoms modified and a promptness in getting up after the fever had left them, closing with some reasons why the antiseptic is the rational treatment for typhoid fever.

DA. L. J. LAUTERBACH of Philadelphia, presented a paper on "Deaf Mutes—Can anything be done by Treatment?"

DR. MURRAY G. MOTTER of Lancaster read a paper on the "Clinical Study of Typhoid Fever."

Three cases; three types; a threefold purpose. These cases have been selected because of the following conditions presented:

Case 1.—*a*, differential diagnosis frequently mistaken; *b*, the type and duration of the pathologic process, and the youthful patient's remarkable powers of resistance—both to the disease and to the misapplied treatment; *c*, the complete and under all the circumstances, rapid recovery, under a strictly *noli-me-tangere* régime.

Case 2.—Three initial complications: *a*, pleuritis; *b*, abortion; *c*, acute nephritis.

Case 3.—*a*, the severity of the initial symptoms; *b*, the grave cardiac complications; *c*, rapid subsidence of the fever, under hydrotherapy (Brandt).

The object of this contribution is to demonstrate:

1. The dangerous, often fatal liability of "pathognomonic symptoms," so-called.

2. The folly of any absolute, invariable, "routine" treatment.

3. The urgent necessity, *a*, of recognizing each case as a law unto itself; and *b*, for treating—not the disease nor the symptoms, *per se*, but—the patient.

DR. W. T. W. DICKSON, of Media, read a paper on "Microbes and Moulds." The Doctor gave a brief account of the deleterious effects of these organisms on animal and plant life; where and in what substances they are found—water, milk, animal and vegetable food, etc. The common nourishment of bacterial growths, spores of dangerous diseases. The susceptibility of individuals of low vitality to succumb to germ diseases and their inability to throw them off were next tersely given. Then he alluded to epidemics, septic poisoning, moulds and fungi that attack fruit, grain and flowers. Ptomaines and serums of cholera, tuberculosis, erysipelas cocci and the antitoxin of diphtheria concluded this highly interesting paper.

DR. L. H. ADLER, of Philadelphia, presented an article on "Treatment of Fistula-in-Ano by Lange's Method or Immediate Suture in the Tract." In no instance was there need to regret the operation. He considered it of decided advantage. Even if primary union is not obtained the patient will be in the same position as if no attempt had been made, whereas if healing ensues the gain is a very considerable one.

On motion of DR. L. H. TAYLOR, of Wilkes-Barre, it was

*Resolved*, That the Medical Society of the State of Pennsylvania considers the registration of births, marriages and

deaths at the central bureau of the Capitol of the State a matter of the utmost importance in the interests of medical science, of public health, of protection to human life; therefore

*Resolved*, That the Society respectfully memorializes the honorable the Senate and the House of Representatives of Pennsylvania in favor of the passage of the bills introduced at the present session, to authorize the State Board of Health to employ a clerk for the registration of vital statistics, to confer the powers of a board of health on the school board of each township, and so to increase the appropriation for the board as to enable it to efficiently discharge this important duty as assigned it by law.

*Resolved*, That copies of the preceding resolutions, signed by the President and Secretary, be at once transmitted to the honorable Wesley C. Thomas, President *pro tempore* of the Senate and the honorable Henry F. Walton, Speaker of the House of Representatives at Harrisburg.

At the afternoon session the Committee on Nominations reported as follows:

President, W. S. Foster, Pittsburg.

Vice-Presidents, John Montgomery, Chambersburg; A. P. Hull, Montgomery; T. H. Sharpneck, Nineveh; A. B. Brumbaugh, Huntingdon.

Secretary, William B. Atkinson, Philadelphia.

Assistant Secretary, C. L. Stevens, Athens; Treasurer, G. B. Dunmire, Philadelphia. In addition, censors, delegates, etc. Next place of meeting, Harrisburg.

The report was adopted.

(To be continued.)

### Illinois State Medical Society.

*Abstract of the Proceedings of the Forty-fifth Annual Meeting, held at Springfield, May 21, 22, 23, 1895.*

[Special correspondence of the JOURNAL.]

(Concluded from page 856.)

In the evening of the first day the President, DR. DANIEL R. BROWER, delivered the Presidential Address, selecting for his subject

SOME ABNORMALITIES OF PHYSICAL CONFORMATION OBSERVED IN CRIMINALS, WITH CAUSATIVE AND CORRECTIVE CONSIDERATIONS, ILLUSTRATED BY THE STEREOPTICON.

The speaker prefaced his remarks by saying that we were living in a marvelous age, and that the closing hours of the nineteenth century were full of wonders. It is not a hundred years ago since the great Pinel established beyond the possibility of controversy the fact that insanity is a disease. Prior to that time lunatics were regarded as either possessed of the devil or as victims of divine wrath. As a result of the rapid progress that has been made from time to time there are now scattered throughout this and other civilized countries hundreds of hospitals for the treatment of the insane, and no one to-day considers it other than a disease, subject to the same laws and governed by the same principles as any other affection. Pictures of noted criminals were then projected upon the canvas, their histories detailed, and the peculiar conformations of the head pointed out. Dr. Brower said there was a great difference proportionately in the size of the brain of a criminal as compared with the brain of a normal individual, and to illustrate this point, a picture was shown from Lombroso's book on "Criminal Woman," which conclusively showed that the average size of the criminal brain is very much smaller. Dr. Brower closed by directing attention to the question of marriage, saying that we should have added to the marriage license certain requirements certified to by some responsible practitioner of medicine, giving evidence that both parties are in good health; that they are not criminals, drunkards or paupers, and that their grandparents were not insane, epileptic, suicidal, or in any way degenerates. With such requirements we would see crime, pauperism, and insanity on the decrease, and would some day witness a race of men and women rising up capable of achievements of which the world has never dreamed.

### SECTION II.

*Surgery, Surgical Specialties and Obstetrics.*

Chairman, DR. WM. E. GUTHRIE, Bloomington.

Secretary, DR. J. A. BAUGHMAN, Neoga.

Section called to order by the Chairman.

### ADDRESS IN SURGERY.

The Address in Surgery of this Section was delivered by DR. DUNCAN EVE, of Nashville, Tenn. He said surgery recognizes its true disciples everywhere. It confesses its obli-

gations wherever benefit is conferred. It owes much to the South and West. It gratefully remembers McDowell as the father of ovariectomy. It pays willing tribute to Crawford Long as the discoverer of ether as an anesthetic. It gladly retains the name of Brasher, who triumphantly performed hip-joint amputation. It, with much pleasure points to Gilmore, as the first to successfully remove a kidney. It recalls with pleasure Smythe's successful ligation of the innominate artery. And to Dudley, Pope, Hodgen, Sims, Wyeth, and many others, refers with equal delight for their many and original procedures. There are two names in this State that surgery honors—Nicholas Senn and J. B. Murphy. For the good of humanity, progress in military surgery has been retarded by an epidemic of peace. It is the duty, however, of the military surgeon "in time of peace to prepare for war." Dr. Eve agrees with Senn that the great factors which will modify surgery on future battle-fields will be: 1, prevention of wound infection; 2, conservative treatment of gunshot injuries of the extremities; 3, prompt, direct operative interference in the treatment of penetrating wounds of large cavities. To this end, we find new and important devices, as in the construction of field hospitals, litter carriers, operating tables, dressing cases, travois, etc. Railroad surgery has established a province of its own. Here is tested the utmost endurance and resistance of which vital force is capable; recovery often attained in the midst of despair; fatal results where injuries appear light and hope is buoyant. Here conservatism can hold complete sway. Within the last few years the treatment of railway injuries has in this respect improved so much that the results mark this era as one of the brightest in the history of the surgical world. On account of our increased knowledge of cerebral topography, intracranial surgery has made great progress. Cysts, or abscesses of the brain can now be diagnosed by the use of a fine aspirating needle, introduced through an opening made in the skull by a watchmaker's drill. The different sinuses can be entered, foreign bodies removed and hemorrhage controlled by means hitherto unknown. We can not fail to observe with much satisfaction the wonderful progress that has been made in abdominal surgery. Of the many operations for intestinal anastomosis, Murphy's button deserves special mention. Sufficient time has elapsed since its introduction to place its use on a sound basis. Within the last year we are led to believe that inguinal colotomy has to a great extent superseded the lumbar operation because of the ease with which it can be accomplished; because a better spur can be obtained in the inguinal region, and because of the patient's more rapid recovery, from the operation.

The dreamy speculations of the past have given way to the realities of fact, and the universe is throbbing with the pulse of progress in every department of thought. We are in the dawn of a new era—an era charged with results tremendous in their issues and their influence upon humanity at large. Who can divine what will be the glory of its noon-day splendor? Indeed, it may be said at this moment, having concluded the journey through the wilderness of the past, we stand upon the mountain of view and gaze into the promised land of the future. Our hearts swell with rapturous emotion, while our minds entranced contemplate the vision that rises before us with all the charm of perfect enchantment.

"For I doubt not through the ages one increasing purpose runs,  
And the thoughts of men are widened with the process of the suns."

DR. W. H. SPARLING, of Moweaqua, read a paper entitled

#### FETAL HYDROCEPHALUS.

The author reported two cases. The first patient was the mother of eight children, all of whom were living and healthy. Having attended her during two previous confinements and knowing her to be unusually expeditious, he did not apprehend any difficulty in her case. The child lived for about half an hour from the time of its birth. The mother made an excellent recovery.

The next case occurred in a woman, 25 years of age, who had been in labor for about twelve hours. This was her fourth confinement in less than four years. All of her former labors had been normal.

The cases are both interesting on account of the rarity of the malformation and the difficulty usually attending labors so complicated. La Chapelle's statistics show only 15 cases of fetal hydrocephalus out of 43,545 labors; but Merriman gives 1 in 900.

The question as to what can cause this disease during fetal life would be an interesting one. Tubercular meningitis being out of the question, the most reasonable supposition would be that it is an unnatural secretion of cerebro-spinal

fluid, which pressing upon the bony walls of the cranial vault arrests their development, this affording ample scope, under the more yielding soft coverings of the head for the formation of a tumor of very large size. The deformity is quite frequently accompanied by spina bifida, as in the author's second case, which might indicate a want of proper development in the bony walls of the cranium and spinal column as encouraging the excessive secretion, and so being the original cause. The head may assume an immense size, cases being on record where it measured twenty-five to thirty inches in circumference.

DR. W. C. BOWERS, of LaPlace, read a paper entitled

#### OBSERVATIONS ON SOME FORMS OF PUERPERAL DISTURBANCES, WITH CASES FROM PRACTICE.

Hemorrhage, septic infection and inflammatory troubles in the puerperal state are often so closely associated, so dangerous to life or in any case to future health, and arise so unexpectedly at times that it behooves the physician to be prepared and alert in every case of obstetrics. The placenta is, in some instances, so roughened that it is nearly impossible to determine whether or not a fragment is left in the uterus and in such cases he had always waited for evidence of such retention, in the form of unnatural hemorrhage, or the passage of small fleshy-looking masses with pain and unsuspicious bleeding. In every case his best endeavors are made to leave no part of the secundines in the uterus by reason of a faulty delivery of them. The author's manner of causing their expulsion is by grasping the uterus through the abdomen with one hand and pressing firmly but gently in the direction of the birth canal, varying the direction of pressure within certain limits until he feels the tumor descending. At the same time gentle traction is made on the cord with the other hand in amount which would be slightly more than necessary to lift its possible weight, taking all the time necessary for its gentle delivery, after which it is carefully inspected. He then gives the woman a drachm of ergot, has the patient and her bed made clean and dry, a binder comfortably applied, and allows her to assume any reclining position in which she is the most comfortable. He believes it a good rule, and adheres to it, not to leave the confined woman under one hour from the birth of the child and not then, unless her condition is good. Remaining with the patient this length of time insures good contraction of the womb and removal of clots from the birth canal, should evidence of their presence arise, thereby lessening the danger of any disturbance later in the puerperium. The author then detailed the histories of two very instructive cases and outlined the treatment.

#### OBSTETRICS IN A COUNTRY PRACTICE

By DR. C. M. NOBLE, of McLean. The country practitioner must necessarily on account of circumstances be a specialist in the various branches of medicine. How well he may succeed in his efforts is quite another matter. In this day of a sepsis the specialist on obstetrics would be very cautious about handling any case which might in any way bring contamination to his maternity patient. It is the author's plan to thoroughly disinfect himself by scrubbing his hands and arms, and washing with disinfectants as if he were going to do an abdominal operation. The finger nails should be thoroughly cleansed and scrubbed with brush and soap. The arms of the operator should be bared and the coat and vest removed. The author believes that in the matter of obstetrics that there is no one thing that is less understood by the laity than sepsis. It is astonishing the amount of ignorance displayed by many people as regards this point; and it seems to him we have no more serious question to deal with. Every obstetrician should impress upon the minds of his patrons the necessity of perfect cleanliness, and teach them the manner by which septic poisons are many times communicated to the parturient woman.

DR. A. C. COTTON, of Chicago, read a paper on "Early Care of the Infant."

DR. ELLEN H. HEISE, of Canton, followed with a paper on

#### THE TREATMENT OF ARRESTED GROWTH IN CHILDREN,

in which she reported cases showing the practical application of the principle that, other things being equal, the horizontal position favors increase of stature in young people. In the case of a healthy young girl, who had remained about the same height from her tenth to fifteenth year, she induced the mother to put her to bed for three months, only allowing her to sit up for a few minutes at a time, but otherwise making no changes in her mode of life. She had not the measurements in her case, but the girl had the satisfaction of outgrowing all her clothing, and by insisting on her

passing several extra hours in bed each day for the next two years she gained the height of her mother and was satisfied. In another case a healthy boy of 16 years of age, the son of tall parents, the height was fifty-seven inches, while the arm extension was two inches more. There had been no appreciable growth for about six years. The horizontal position, continued for three months, resulted in an increase of three-quarters of an inch in height, and Dr. Heise confidently believes that the removal of longitudinal resistance to the growth of the skeleton will prove amply advantageous in those cases in which normal growth is too early arrested.

Dr. J. E. Covey, of Lexington, read a paper on

#### THE CARE OF THE PARTURIENT WOMAN.

To act intelligently the physician should be able to recognize the physiologic limits of the symptoms resulting from labor. He believes in the care of the puerpera that the physician will have done his whole duty when he surrounds his patient with those conditions where nature has the least opposition in her reparative processes. Consequently a warm dry bed and perfect rest will be the first things he will secure for her. The child should be kept out of the room for several hours. The room should be darkened and the patient allowed to sleep. No one should be allowed in the room but the nurse. The air in the room should be kept pure and at an even temperature. Cleanliness in all instances should be rigidly enforced. Unless the lochia becomes putrid, or there is dryness and soreness of the genitalia, he does not believe that frequent injections are necessary. The external parts should be bathed with a warm antiseptic solution, and should the secretions become putrid or the vagina become dry and tender, warm carbolized injections will not only destroy the fetor, but give great comfort to the patient. The patient should be directed to empty the bladder during the first twelve hours, and failing to do so, should be catheterized. Diet must be light for several days and should be selected according to the requirements of the patient. Not later than the third or fourth day the bowels should be evacuated. As to the time when the parturient shall leave her bed, the author's rule is to keep them in bed for two weeks and not allow any active exercise for six weeks longer. Lacerations of the perineum will occasionally occur in the practice of the most skilled accoucheur, and he closes them immediately after labor, or within twenty-four hours.

#### ENDOMETRITIS.

A paper on this subject was contributed by Dr. S. M. Wylie, of Paxton. After defining endometritis, the author said the earlier the cases are recognized, and the more energetic the treatment, within certain limitations, the more satisfactory the results will be. The preliminary treatment by hot douches, boro-glycerite, cotton tamponade or ichthyl glycerine, 20 per cent. on wool tampons, giving support to the uterus and ovaries, taking off tension from the uterine ligaments and by pressure as well as exosmic influence, removing plastic products about the uterus and supporting pelvic vessels, will do much toward relieving the congestion and hypersensitiveness and lessen the dangers attendant upon the more radical measures necessary for their relief, which is, first, curettage, which offers the best treatment at our command. After thorough curettage, the application of pure carboloid acid to the entire cavity is used, or the gentle injection of fifteen or twenty drops of compound tincture of iodine, with a Carl Braun syringe, following this with a thorough uterine irrigation with sterilized water, or a 1,000 aqueous sterile solution of iodine without the previous application of the carboloid acid or iodine.

The general treatment of these cases after the immediate causes have been removed consists in keeping the bowels unloaded, administration of proper food that will be easily digested and assimilated, bathing, massage and a free use of water internally for drinking to flush out the sewer gates and unload waste tissue products. Uterine drainage should be regarded as of the first importance, and the author uses iodoformized gauze in all acute septic cases for packing the uterus, as well as in the chronic cases, where repair of the cervix has not been performed. Curettage should be accompanied by a repair of both the cervix and perineum if torn. Dr. Wylie has no faith in so-called intra-uterine medication in this class of cases with mops or applications of acids, astringents and other medicines.

Dr. J. A. Freeman, of Millington read a paper entitled

#### THE INTRA-UTERINE REMOVAL OF MULTIPLE MYOFIBROMATA,

in which he said, after referring to the various methods for removing these growths, that tumors as large as medium

sized oranges, which grow outwardly, or subperitoneally, and which have but a thin, if any, muscular external covering, can be successfully removed *via* the intra-uterine passage. He had in several instances removed quite large ones successfully by that method. He showed fifteen small tumors which he had removed at one sitting from a patient from whom he, twelve years previously, dispersed or caused to shrink to a size so small as not to be felt, a tumor as large as his fist by electrolysis, and which never grew again. After this tumor had disappeared he found two other (smaller) ones growing which he caused to project internally into the uterine cavity by injections of ergot and the internal administration of the agent, and finally removed them. He raised the question, Is it not best to remove these tumors *via* the intra-uterine and vaginal canals in all cases in which it can be done, thereby leaving the patient without any subsequent annoying adhesions, and capable of performing all of the functions natural to a perfect woman?

Dr. O. B. Will, of Peoria, read a paper on

#### SOME GENERAL CONSIDERATIONS ON DIAGNOSIS IN GYNECOLOGY.

He first called attention to the great desirability of devoting a larger proportion of time and effort to the attainment of diagnostic skill; and, also, to the end of studying more closely the actual state and condition of the local system, as well as its individual organs, under circumstances of apparently perfect, or approximately perfect, general and local health. The author then briefly presented the essential features of three cases in illustration of his point of support, which served rather to suggest a lack of attention to diagnostic landmarks and careful scrutiny, than downright ignorance; but viewed in either light, they are rife with information and lessons of a practical character, in that they evidence the necessity of careful, thoughtful diagnostic skill as the very basis of a valuable reputation and a successful therapy. In the diagnosis of gynecologic affections, as of those of other systems of the human economy, the object is to determine the kind and degree of departure from the normal anatomical and functional attributes of the several organs, and their relationship to each other, without the involvement of serious disturbances.

In conclusion, Dr. Will said we should aim at an accurate and decisive diagnosis in all cases. To that end we should study well the attributes of normal structure, form, position and association. To the right minded physician no difficulty need be experienced in securing opportunity. We should use all the means at our command, both natural and artificial, bearing constantly in view the ideal method, embodying preservation of tissue integrity and obedience to the aseptic and antiseptic principles of the age and time.

Dr. CASEY A. Wood, of Chicago, read a paper entitled

#### FOREIGN BODIES IN THE EYE.

The responsibility assumed by the surgeon who undertakes the care of an eye whose envelopes have been penetrated or ruptured, is greatly increased by the fact that not only the vision of the injured eye, but that of the second eye may be at stake. The dreadful possibility of sympathetic or migratory ophthalmia should always be borne in mind. This disease runs such a chronic and painful course and is so disastrous in its effects that when once encountered it is never forgotten. It was not the author's purpose to weary the members with a discussion of certain theories respecting the pathology of ophthalmia migratoria, but rather to indicate some of the principles commonly regarded in dealing with certain ocular injuries and to illustrate these with some cases that had come under his own observation. First of all, ocular traumatism may be empirically, but, he thinks, usefully and practically divided into three classes: 1, those that are serious or not from the standpoint of sight only—where we are mostly concerned in asking whether or not the patient is likely to have useful vision in the injured organ; 2, those that threaten the integrity of the second eye whose vision may at the time be fairly useful. Here the eventual vision of the injured eye must be subordinated to the protection of the fellow organ; 3, those cases, probably the most numerous, in which sight is destroyed in the injured eye and anxiety may be felt in respect to the vision of the other eye.

The author then reported the histories of three cases which belonged to the first class. As examples of the second class he also briefly detailed the histories of three cases. Of the third class, he gave but one example, and said that injured eyes of this class should always be removed.

As an aid to prognosis and treatment, he suggested the following rules:

1. As long as the wound heals without difficulty and no

sympathetic irritation persists I would treat with rest and antiseptics and would not remove any eye whose injury is confined to the cornea, iris and lens.

2. I would not enucleate an eye containing a foreign body where the injury confined to the tissues of the foreign body, could be removed.

3. I would not remove an eye containing a foreign body if there was no injury in the ciliary region, and the missile had passed through the posterior wall of the globe.

4. I would not immediately excise an eye injured by small shot (which are usually aseptic missiles) even if the wound were in the ciliary region, provided the patient could occasionally be seen by an oculist.

5. I would always excise an eye that contains a foreign body that could not be removed.

6. I would excise an eye in which the ciliary body had been injured, even if the sight were not much affected thereby. The only exceptions I would make to this rule are small gunshot wounds, in cases where the second eye is useless or had been removed, and those instances in which there is no continued uveitis of the injured eye, provided always that the patient could be frequently seen by an oculist. For the average man, however, excision or exenteration would be by far the safest procedure in the last instances. Where loss of sight goes along with ciliary involvement there can be no argument in favor of retaining the eye.

7. When once ophthalmia migratoria has set in, it is wise to retain the injured eye if there be any sight in it, as eventually it may be the better of the two.

8. It is safe and proper to remove all tender and inflamed eyes of adults where vision has been lost from a penetrating wound in whatever region of the globe.

9. It is highly desirable to retain the eyeball in patients under 20 years of age, if it can be done with safety to the better eye, since earlier removal of the globe retards the growth and development of the corresponding orbit and greatly alters and mars the facial expression.

(To be continued.)

#### American Electro-Therapeutic Association.

Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 809.)

#### DR. NEWMAN LAWRENCE, M.I.E.E., read a paper on HYDRO-ELECTRIC METHODS, PHYSICS AND APPLICATIONS.

##### INTRODUCTION.

The term "hydro-electric methods" is, I take it, but a sort of modern glorified edition of the old-time "electric baths." The advantage of its adoption seems to lie mainly in the fact that it offers to the lay mind a halo of obscurity through which there is little chance of recognizing any connection with so common and so medically-despised a "method" as the electric bath.

Judging from what I have seen and heard, the medical profession have very little respect for electric baths in America, and are content, for the most part, to leave the administration of them to the attendants of Turkish baths and similar institutions, regarding the whole business as either a fad or rank quackery.

Looking at the matter as an electrician, it seems to me that electric baths and especially modern developments now designated hydro-electric methods are worthy of better attention and study. For, if it be granted that physicians sometimes wish to place their patients under electrical influence, either local or general (and the very existence of this Association proves this to be the case) it is certain that one way by which this may be done is by electricized water and accomplished by it, moreover, in a manner widely differing from other "methods," as to physical conditions.

Where physical conditions differ, it is reasonable to suppose that physiologic and pathologic resultant influences may differ also; therefore, without in any way trenching upon the therapeutic value of these methods, it may be advantageous to consider briefly some of the physical conditions and problems of hydro-electric therapy.

The questions here dealt with, in accordance with the request of your Secretary, are those relating to the use of constant current only; thus it is manifest that it will be impossi-

ble to avoid going over some ground which is also common to the use of other forms of current.

The subject seems naturally to divide itself into the following heads:

- A. Apparatus required.
- B. The current employed.
- C. The methods.
- D. The patient (considered electrically).
- E. Problems.

And I will ask your attention to each in turn, for a few moments. To consider them fully would take more time than lies at my disposal but I have endeavored to set forth an outline, based upon broad principles, fundamental facts and practical experience, which may prove useful in assisting any member of this Association who desires to turn his attention to the subject.

##### A.—APPARATUS.

A bath tub of porcelain, slate or wood, or perhaps of compressed paper—any way, of non-conducting material, if it is intended to use it for dipolar baths. The German pattern of bath tub is of oak, ovoid in shape, four feet ten inches long and two feet six inches wide. Height at head, one foot eleven inches; at foot, one foot five inches. I have found in practice that the tub may be conveniently a few inches longer and three or four inches narrower.

Electrodes in the German baths are fixed in various positions and communicate with a switch board by means of wires or conducting rods passing through the sides of the tub. This perforation for conductors in the sides of the tub always seems to me a source of weakness. However carefully connected, they often leak water sooner or later and, when once fluid leakage commences, electrical leakage can not be prevented. I much prefer electrodes which may be placed in the water in any position required and connected by insulated wires to terminals outside the bath tub. These, if of suitable size, may be made to answer all the purposes of the fixed German electrodes and entirely obviate the objections above referred to. An adjustable band of strong webbing to support the shoulders when the patient reclines in the bath, having leather straps and buckles or loops and buttons to regulate its length, is a convenient adjunct to the bath tub.

Of electrical apparatus, besides the battery or other source of supply, a switch board, a cell collector or rheostat or both and a milliampere meter reading up to 300 milliamperes are necessary.

I have dealt more in detail with the electrical apparatus under the head of "current employed," but it may be well to state here that any such apparatus used should be of the best description. It need not be elaborate but it must be good and reliable. Such apparatus may be rather costly, as regards first outlay, but once purchased and properly installed it will outlast several sets of inferior quality besides being throughout far more satisfactory to work with.

##### B.—CURRENT EMPLOYED.

This, by the conditions of our program must be what is known as constant or continuous current, but the source of supply may be either a battery or a dynamo or as drawn from the street lighting mains. If a battery be used it must be of sufficient power, i.e., it should consist of 40 to 60 cells having an E. M. F. of not less than 1 volt per cell, and these cells should be of fair size. Three-pint or two-quart Leclanche cells will do very well or any similar simple kind of cell; but complicated and not-get-at-able makes should be avoided. If larger cells are available, they may be used but it must not be overlooked that the size of the cell does not determine its E. M. F., and therefore no increase of size will do away with the need for a number of cells. At least 40 of any kind are needed, be their size great or small, but large cells possess more current capacity and therefore will last longer in proportion to their size. With a battery the means of control are generally either a cell collector or a rheostat or a combination of the two.

All control should allow of very gradual increase and decrease of the current. A cell collector therefore should not switch on more than two cells at a time. Even these small stops must be made without sudden jerks or the least semblance of shock to the patient in the bath, and this is extremely difficult to obtain in a cell collector. I have tested many and can not say that I have found one which satisfactorily overcame the difficulty.

A rheostat, on the other hand, of sufficient power, put in circuit with all the cells, becomes in this respect a perfect controller but is open to the objection, recently brought forward, that current passed through it is more painful, because all the E. M. F. of the battery passes to the patient, the total

energy administered (for an equal current supply) is greater and hence more pain may be produced. To what extent this objection holds good I am not in a position to say, but should expect it to be somewhat counterbalanced by the therapeutic advantages of the increase of total energy; while at the same time it is obvious that less current supply may be used and so the total energy made the same as it would be with greater current supply and lower E. M. F.

A combination of both cell collector and rheostat is sometimes recommended, and may be made to obviate both the difficulties above referred to, though its use is somewhat complicated and in the hands of an ignorant or careless operator may be distinctly dangerous. As an illustration of the latter point—suppose the cell collector acts by 10 cell steps and the rheostat controls within such steps, it will be necessary to move the rheostat switch so as to put in much more resistance previously to switching on ten more cells in order to prevent too great an influx of current supply. A double process of switching which could very easily be muddled so that the patient receives a severe shock.

*Dynamoes.*—In institutions, hospitals and other large establishments having their own electric plant for light and power, the current so generated may be employed for hydro-electric purposes, provided proper precautions are observed to prevent accidents. On no account should it be considered safe to pass such currents direct through a bath with a rheostat only in circuit. The currents used in the dipolar bath are large (sometimes 200 or more milliampères) and their sudden break or increase might have very serious effect upon the patient. There are, however, controllers in the market which are much more than simple rheostats and in accordance with a suggestion, first made I believe by Dr. W. S. Hedley, of Brighton, England, in the *Lancet*, April 9, 1892, include a special safety automatic cut-out and a *shunt circuit for the patient*. The shunt or divided circuit is a very important safeguard, for, by the suitable adjustment of resistance in the two arms, the current in the patient's circuit may be made any desired proportion of that in the main circuit, and the automatic cut-out effectually prevents the passage of any greater current than the maximum to which the apparatus may be set for the time being.

M. Gaiffe, of Paris, has introduced a controller based upon the divided circuit plan which is very simple. To the best of my recollection, it consists of two arms of moderate resistance upon which move sliding contacts forming the terminals of the patient's circuit. By adjusting the contacts the E. M. F. of the patient's circuit may be anything from 1 or 2 volts up to the full voltage of the supply.

*Street Mains.*—In using the current from the street supply mains the methods of control are those given for use in institution installations. The two cases are almost identical and though the E. M. F. of the supply may differ, yet it would in all cases be greater than that required for hydro-electric application and therefore would have to be controlled.

*General Precautions.*—In all electric bath installations it is absolutely necessary to pay great attention to insulation of all leads and conductors. Water is a fairly good conductor and metal pipes are excellent conductors. Where electric light leads are about, in the same building, it is very common to find an "earth" or "ground" more or less marked, the consequences of which may be very serious. I have seen a patient, when in the electrical water, receive quite a shock on touching one of the water taps that supplied the bath, and this though on careful testing it was found that the insulation of the bath installation itself was perfect. In order to obviate this risk I recommend that the water taps and any others in metallic connection with the earth be placed so far out of reach that no person can touch them when in the bath or, if they must be near, that they be made of porcelain or glass, or at least well coated with some insulating substance. Damp woodwork, whether of wall, floor or bath casing, is a fruitful source of electrical leakage; the dry wood is in most cases a sufficient insulator. All switches, controllers, measuring instruments, etc., should be placed well out of the range of splashes and may be advantageously protected by a box with glass case front.

#### C.—METHODS.

These may be dealt with under two heads, dipolar and monopolar. The older forms of electric bath seem to have been, with little, if any, exception, administered with both poles in the water. Hence the name, di-polar. There are varieties of the dipolar bath in which one of the electrodes is brought into contact with the patient's skin and which therefore may, to some extent, be called monopolar, but it seems to me more correct to class all methods as dipolar

where the electrodes are placed under water, no matter whether they be also in contact with the patient or not. It follows that monopolar baths or methods are those in which only one electrode is placed in the water. The electric douche may be either dipolar or monopolar, but it is more generally the latter.

*Dipolar.*—The dipolar bath consists in the complete or partial immersion of the body in some conducting fluid, usually water, and the passage of a current through the composite conductor, fluid and body, by means of electrodes immersed in the fluid and generally kept apart from the patient's body. Sometimes one or both of the electrodes are made to touch the patient, while still kept under the water, with the idea of concentrating the lines of force at a given spot.

*Monopolar.*—In this form of bath, one electrode only is used in the bath water and the other is placed upon some part of the body not immersed. By this means either pole may be made the more active by concentrating the current at the non-immersed pole and widely diffusing at the immersed pole. For instance, if a patient be sitting in a bathtub full of water and one electrode be placed in the water and the other attached to his shoulder, the current will be diffused more or less over the whole of the immersed portion of the body but the entire current, be it great or small, must pass through the shoulder under the other electrode and is therefore concentrated upon an area many times smaller than that of the immersed body.

The monopolar form of bath may be used under circumstances which preclude the dipolar, for, while the latter requires a bathtub of considerable length and depth, the former may be efficiently administered with a sitz bath or even a good-sized basin and a sponge. A little water in the tub or basin covering a plate electrode forms the diffusing pole and the sponge, duly connected electrically, makes a convenient concentrating electrode. The patient sits or stands, as the size of the vessel will permit, while the sponge electrode is applied to such parts as need the special localization of current or is passed gradually over the whole body so that each part, in its turn, receives the stimulus of localized current. It will be readily understood that both forms of bath are capable of many variations to suit special cases. The general conditions only are here referred to.

*The Douche.*—For a long time it was doubted, in England at any rate, if electric currents could be administered to the body by means of fluid douches in any other form than in one strong jet or stream. I remember having some correspondence with the late Dr. W. E. Stevenson, Physician of the Electrical Department at St. Bartholomew's Hospital, London, on the subject, and in offering to prove to him that, with a properly constructed rose or sprinkler, electrized spray might be obtained. Unfortunately, the early death of that distinguished and careful electro-therapist prevented the proposed demonstration. Shortly after, however, I was able to prove the matter to Dr. W. S. Hedley, with the result that some interesting experiments, which leave no doubt on the subject, are published in his admirable work on "Hydro-electric Methods in Medicine." All that is necessary to insure that the water or other fluid is electrized when it reaches the patient is to have the nozzle so constructed that the jet or jets of water form continuous streams for a reasonable distance after they leave the metal conductor within the nozzle. A little attention to the mechanical construction of the nozzles will secure this. Broken up spray will not conduct the electric current any more than a broken up copper wire would do. There must be fluid continuity if we would have electric continuity. Dr. Hedley records that with a 2-inch rose nozzle, having forty-nine perforations, he was able to administer 5 milliampères of continuous current to a patient when the nozzle was held one inch from the body, with plain water. When salt was added to the water 7.5 milliampères passed over one and one-half inches with that particular nozzle; while with a single jet nozzle he passed 20 milliampères over eighteen inches. With coil current the effects were much more marked, and when treated with a telephone in circuit showed the presence of current at very great distances.

Measuring instruments, or at least current indicators, are a necessary part of any electric douche plant, for without them it is impossible to know to what extent the apparatus is working or even if it is working at all. Speaking from personal experience and numerous observations, I think the douche application stands alone as a means of producing maximum concentration and localization of current with

minimum pain. It is essentially an instrument of precision and in skillful hands is capable of graduated and modulated effects through the widest range. It is suited to internal as well as external applications and, owing to the perfect way in which fluids penetrate all the interstices of the orifices of the body and the electrization of the whole fluid, the electric douche forms a sure means of electrizing parts which could hardly be brought under the influence of the current by any other form of electrode.

I am strongly of opinion that the electric douche is worthy of careful attention and test by physicians, especially where internal electrization is required, and I look forward with pleasurable anticipation to the paper by Dr. Cleaves, who I understand has found the electric douche a most valuable adjunct to other methods in certain cases.

#### D.—THE PATIENT, CONSIDERED ELECTRICALLY.

It is manifest that the usual figures given for the resistance of the human body do not hold good when that body is immersed in fluid. Roughly speaking, the greater the portion of the body immersed the greater will be its conductivity and the less its resistance, but other factors have this influence. The body with dry skin possesses resistance several hundred times greater than that of plain water at ordinary bath temperature, say 95 degrees F. The difference is still greater when medicated fluids are considered. The resistance of the body rests mainly in the outer skin. Consequently, if the body be immersed in either plain water or medicated fluid its resistance will be reduced almost immediately and after being well soaked in the fluid the resistance may be brought down to between three or four times that of the fluid. Dr. Hedley tested a patient under bath conditions, as nearly as he could imitate them, and found his resistance to be 540 ohms, while that of the water alone was 140 ohms. It seems practically certain that the resistance of the body is always much greater than that of the bath water, and, even after several minutes soakage, is generally quite three times greater than the resistance of the water in which it is immersed. From this it is manifest that it by no means follows that because a certain battery will pass a certain current strength through a bath of water before the patient is placed therein, it will pass the same current strength when the patient is in position. It will do nothing of the kind, and this leads at once to one of the most interesting and complicated problems in electro-physics.

#### E.—IN A DIPOLAR BATH.

Given a bath tub of water, of known resistance, with electrodes of a certain area and a patient of known resistance before immersion, what proportion of the current strength will pass through the patient when he is immersed in the fluid, and the current is passed from one electrode to the other (a) when neither electrode touches his skin and (b) when one or both touch him under water? Numerous investigators have sought a solution to the problem, but so far, I believe, without success, though some have arrived at what looks like a reasonable approximation. The absence of an accurate determination is to be regretted for without it no reliable data for dosage in the dipolar bath can be established. Dr. Hedley, after elaborate and careful experiment, concludes that the body receives about 5 per cent. only of the total current. Steavenson and Jones previously stated in a broad manner and without giving any experimental data that the proportion is about one-eighth, but the mere bald statement of those last named can not be allowed to weigh against the very full and detailed investigation of the former. Still I can not say that I accept Dr. Hedley's figures as conclusive. I have repeated many of his experiments, conducted others of my own, and tried in many ways to devise some arrangement for measurement which shall fully meet all the conditions, but there is so much that is varying and always variable that the  $x$  of the problem becomes a sort of hydra-headed monster bristling with unknowns in all sorts of unexpected places. For instance, though the diffusion of current in the water alone may be traced, and the lines of force mapped out with fair accuracy, the presence of the body at once disturbs the lines and deflects them or at least many of them from their direct course. This deflection and consequent alteration of the field might be calculated if the resistance of the body, when immersed, were known, but this, the key to the whole problem, has yet to be determined.

Again, the presence of the body raises the level of the water and consequently in those bath tubs where large electrodes are fixed, causes increased electrode surface to come in contact with the water. Thus another disturbing element is introduced. Yet again, with constant current the conduction is electrolytic in the water, and more or less so, in

the body. This means counter E. M. F., and must assume appreciable proportions while the body resistance is being reduced by soakage.

The only way in which this problem can be solved is, I think, by means of specially constructed apparatus wherein the body and the fluid could be studied separately without being separated more than momentarily. Such apparatus I have not yet been able to secure, though I do not think it would be difficult to devise. In the meantime, Dr. Hedley's figures form a useful working basis and enable the physician to have some idea of the proportion of the current which reaches his patient.

Another interesting question is that connected with what are termed local dipolar applications, *i. e.*, bringing one or both electrodes into contact with the patient under water. If the patient was a better, or even as good a conductor as the water, doubtless much useful concentration of current might result; but, as the water has the lesser resistance the current from the electrode must to a large extent radiate outward through the water and away from the limb or other part of the body which it is intended to benefit. Of course when a limb is just between the electrodes the field around it, and to some extent through it, must be stronger than when the electrodes are some distance away but may not this be compensated for or even overbalanced by the fact that the transverse resistance of a limb is far greater than its longitudinal resistance. Having regard to these various points, it is clear that the dipolar bath is, physically, a very inefficient apparatus from the electrical point of view, because only a very small portion of the current used passes through the patient. Therapeutically, however, dipolar baths have a good record, and many physicians are content to waste current in order to produce the special effects that experience tells them is beneficial in many cases.

Monopolar baths, on the other hand, are very efficient, for all the current used *must pass* through the patient. Electrically there be no waste in the process and, if reasonable attention is given to the insulation there will be practically no loss in the connections.

It may be thought that I have, in this paper, given undue prominence to the difficulties connected with hydro-electric methods, and so discouraged their adoption and development in America. I have no intention of doing so, for, as I have more than once clearly stated in the paper, I believe that hydro-electric methods offer to the physician electrical opportunities which can not be obtained by other methods and therefore I would do all I can to encourage their development. It is to further this end, and not to hinder it, that I have given prominence to difficulties and dangers which it would be unfair to pass lightly over and which the true scientist will find pleasure in combating and overcoming.

(To be continued.)

**A Case of Genito-urinary Tuberculosis**, presented at the *Berliner Verein für innere Medizin*, Dec. 10, 1894. Clinically, in addition to the manifest pulmonary and laryngeal phthisis, characteristic signs of genito-urinary tuberculosis were present, and, in particular, the pathognomonic evidence, tubercle bacilli in the urine in abundance, and arranged almost without exception in little heaps and groups, as is peculiar to these bacteria in the urine. Anatomically, a very interesting condition was presented, both in the very unusual intensity which the process attained in the affected parts, and in the limitation of the disease to one-half of the body from the bladder upward. The left kidney was permeated by a series of abscesses with caseous contents. The left ureter was converted into an immovable, rod-like structure, wholly degenerated from tubercle. The bladder was a mass of ulceration, its surface strewn with caseous and chalky particles. Tuberculous foci were found in the prostate, left seminal vesicle and left epididymis. The right kidney and ureter had remained intact. In the localization of the process in the left kidney, the case might be assumed as the rare descending type of genito-urinary tuberculosis, but for the fact that the extirpation of the right epididymis was performed five years before, and vesical symptoms did not begin until long after.—*Centralblatt für innere Medizin*.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JUNE 8, 1895.

THE ADMINISTRATION OF CHLOROFORM.

RICHARD GILL, in the last volume of Saint Bartholomew's Hospital, has an article entitled "Notes on Chloroform Anesthesia," which, as it is based on large experience, will be read with interest. In conclusion, Mr. GILL asks the question: "What is the best sign to be guided by, when chloroform is administered?" He comments thereon as follows:

"This is a question which does not admit of a general answer, because different rules have to be obeyed during the induction of anesthesia, during long and short anesthesia, and also when alterations are made in the patient's position. This much, however, may be stated concerning the induction of chloroform-anesthesia: the pulse may be ignored, but the respiration must be assiduously watched. How do we know that the patient is unconscious? By the alteration which the breathing undergoes; it is no longer controlled by the will; it has become automatic. But the patient being unconscious, how do we measure the amount of chloroform which is safe for the purposes of continued anesthesia? By the size of the pupil. Sometimes the pupil is large and sometimes small, when unconsciousness is induced. The large pupil may mean narcosis; the small pupil is always the sure sign of safe anesthesia. The small, contracted, or pin-point pupil is, then, the measure of anesthesia, and is unquestionably the safest sign to trust; for during anesthesia, and especially during prolonged anesthesia, the respiration may become imperceptibly labored, and its new character may escape detection, the more particularly by inexperienced administrators.

"But while the breathing is becoming impeded, the

pupil is slowly dilating and losing its sensitiveness. This change in its character indicates that the extreme limit of anesthesia has been exceeded. The stage of narcosis has been entered upon, and it is the pupil, not the respiration, that has given the signal. When the patient's position is altered, as from the supine to the lateral, the breathing becomes obviously changed. To rely entirely on the respiration would, in this new condition, lead to a return of consciousness. Here the pulse is of use in determining the right amount of chloroform. Is the pulse of no further service? Undoubtedly. In prolonged operations it is the first to give signs of depression, and must be watched with care and attention, so that when it begins to fail, those means may immediately be put into action which are best known to maintain the flagging energies of the patient. It is thus collapse is anticipated, and, if not prevented, in some degree mitigated."

"LOIMOGRAPHIA," A DESCRIPTION OF THE GREAT PLAGUE.

The Epidemiological Society, in its current thirteenth volume, has a contemporary sketch of the London Plague of 1665. This valuable paper has been rescued from the hidden riches of the British Museum, at the instance of Dr. JOSEPH FRANK PAYNE, the late President of the society named above.

The historian was MR. WILLIAM BOGHURST, an apothecary, who sold drugs at the "White Hart" shop in the parish of St. Giles-in-the-Fields. The manuscript was prepared for the printer, but it was either not printed or was consumed in the great fire, as were many other newly issued works.

BOGHURST was something more than a book-making apothecary. His book speaks of his independence, his skeptical analysis of current theories, his personal investigations at the bedside, and philosophical vein withal. He says of his undertaking to write on the Plague that there were many persons able to do the work better, "who might have saved me the trouble, and have done it better, especially if they had not been timorous, and like Foxes in a storm, run to the next borough."

The author traces the Plague to cases that had existed in London for three or four years prior to the great prevalence, rather than to a recent importation from Turkey through Holland, as is asserted by other writers. He recounts some of the numerous explanations of the rise and progress of the disease, rejecting not a few as fanciful and as drawn from a lack of actual observation. Of himself he says: "I have writt nothing from hearsay, or from bookes, or from the testimony of others, or of my own conceit, but all and only from experience and triall."

The diversity of causes he locates in the "fæces of the earth, and it always arose *ab infra et non de supra*"

by a fermenting action "extracted into the Aire by the heat of the sun and diffused from place to place by the winds." Of the post-mortem appearances of the disease he has little to say, for he was too busily occupied with his large practice among the pest-stricken ones to have time for that line of inquiry. He places much dependence upon the record of the pulse of the sick, and sat for considerable periods at a time holding his patient's pulse. Of his treatment the editor has taken much pains to give the palliatives, poultices and plasters upon which BOGHURST relied. That the latter was not bound up to a routine of practice may be seen from his saying that "one way of Cure will not serve for all, but we must do as contingencies do divert us. By continually following of one course, occasion is given to every Mountebank, tradesman and ignorant Old Woman to practice. The Good and the Bad fared all alike, and if any fared worse, I think it was the Good." He notices the presence, and in certain patients the intercurrent of spotted fever.

The increase of vermin, meaning rats, is noted by the author, a condition paralleled in the late plague in the Chinese cities, with this difference, that our modern interpretation of the phenomenon implies that these animals leave their haunts and come to the surface to die.

Of the "Prognosticks" of the Plague, upon which so much concern and intellect—in the field of fancy and panic—were expended, BOGHURST writes but briefly. His own time being occupied with bedside work chiefly, he was not led away by "other men's weak observations." He contents himself with a general confession of ignorance in scriptural phrase: "I think," says he, "it may be said of the Plague as is said of the Wind, that it bloweth where it listeth, and we hear the sound thereof, but know not whence it came nor whither it goeth."

The word "Loimographia" has an unaccustomed look, but it is recognized in the larger lexicons as one referring to "a description of the Plague and other infectious diseases."

#### THE TREATMENT OF FRACTURED PATELLA.

Which is the best or most successful procedure to adopt in treatment of fractured patella, is a question which has been frequently discussed, but which still remains unsettled. The reasons for this are not attributable to any fault on the part of surgeons, notwithstanding the proverbial difficulty about doctors agreeing, but they are inherent in the very nature of the clinical problem. This was recently very well illustrated in a discussion by the Section on Surgery of the College of Physicians of Philadelphia. At the meeting held April 12, Dr. J. WILLIAM WHITE presented three cases in which brilliant results had followed BARKER's operation. All of them were

in adult males, engaged in mechanical pursuits, who had received simple transverse fractures of the patella. All were confined to bed only a few weeks, two had left the hospital and returned to work inside of two months and one in eleven weeks from the time of injury. The method of BARKER, as described in the *British Medical Journal* (Feb. 27, 1892), is to encircle the patella with a vertical, antero-posterior silk ligature which, when tied, holds the fragments firmly together. The operation is done subcutaneously and the ends of the ligature are cut short. The original operation was slightly modified by PROFESSOR WHITE.

MR. BARKER uses a long needle, which enters the tissues below the patella and passes through the tendon, or ligamentum patellæ, into the joint, and being carried upward behind both fragments emerges from the tissues above the upper fragment. A stout, twisted silk ligature is now threaded through the eye at the point of the needle, and is carried downward behind the patella. The needle is then re-introduced into the lower opening and carried upward again, but this time in front of the patella; now being brought out at the upper opening, it is again threaded so as to carry the other end of the ligature down in front of the patella and out of the lower opening. The fragments are then approximated carefully and the ligature tied with a surgical knot, the ends cut off short, and antiseptic dressing applied.

PROFESSOR WHITE always makes a puncture with a knife, so as to secure an opening through the tendon large enough to discharge clots of blood and serous fluid, before introducing the needle; thus reducing tension and favoring early repair, by drawing off the effusion from the joint.

In the discussion which ensued, the admirable results in the cases submitted were fully acknowledged. The reporter was complimented upon the complete restoration of function, and upon the reduction in the length of treatment. Most of the Fellows who examined the cases thought that the union was bony, others considered it ligamentous, but all agreed that it was firm, and that the results could not be surpassed by any other method of treatment.

In opening the discussion, PROF. JOHN ASHHURST JR., said that a good deal of stress should be laid upon the character of the injury in speaking of the treatment for fractured patella, since a fracture of this bone in one case is not the same thing as a patellar fracture in another case. He laid especial stress upon the point of diagnosis: whether or not the injury is limited to the patella. If the lateral ligaments are torn, or other structures of the joint injured, the consequences are quite different from a simple fracture. The functional importance of the patella (which is only a sesamoid bone) has been greatly exaggerated. If there are no complications, walking is not made impossible, as is generally thought to be the case.

If the patella be broken by direct force, and there are no complications, the disability is very slight, and the patient retains the power to extend the leg as well as he did before receiving this injury. After excision of the patella, in gunshot wounds, the function of the quadriceps tendon and movements of the limb are preserved. The patient can walk, but does not do so because it hurts him. He concluded that a great many cases of fractured patella will recover and have very useful limbs, without special care. His own experience had been that, in simple fracture, of the patella, in the great majority of instances, a satisfactory result will be obtained by the ordinary and usual methods of treatment. The matter of separation of the fragments may mean very little of consequence, since there have been cases with several inches of separation and yet the patient had not been prevented from walking about and attending to the ordinary duties of life, even when they are as active as those required of a sailor in going up aloft. This is because the fibers of the quadriceps tendon are not broken. When this complication occurs, the disability is more marked, and surgical intervention becomes necessary. He preferred mechanical methods by splints, a fixed dressing and rest in bed; when more is needed he would give the preference to those methods which do not open the joint to those which do.

The contention of MR. JONATHAN HUTCHINSON, that the separation of the fragments has for its sole cause the effusion into the joint, he considered just. Since the superior fragment is forced upward by the effusion and not drawn up by muscular action, he said that all that is necessary to do, in order to secure apposition, is to remove the effusion by aspiration of the joint. In the great majority of cases nothing more is needed than to apply splints and elevate the limb. A firm fibrous union is just as satisfactory to the patient as that obtained by any cutting methods, and he was very skeptical about bony union in any of these cases. SAYRE'S case was referred to, which in the dry specimen appeared to be united by bone, but after maceration for a short time, it was found to be ligamentous. The arguments with regard to bony union he regarded as misleading and theoretical; the ligamentous union is just as good. The disability after fractured patella, PROFESSOR ASHURST attributed not to inability to throw the limb forward, but, frequently, to moderate ankylosis, owing to the fact that some form of apparatus is generally worn for six months or more, and that, as a result, some stiffness will result which, however, will subsequently pass off by exercising the part. He did not approve of the use of MALGAIGNE'S hooks, but spoke favorably of a method which consists in placing an acupuncture pin transversely through the soft tissues above the upper fragment of the patella, and a second one below the lower fragment, and uniting them

with a ligature thrown around both pins in a circle, or ellipse.

DR. KEEN presented a patient, seen some time after the injury, in which the fragments had been so widely separated that they could not be brought together. He had practiced the method of scoring transversely the lower surface of the quadriceps, suggested by TREVES, but still could not bring down the upper fragment sufficiently. He then adopted the novel expedient of lengthening the lower tendon by chipping off the tubercle of the tibia and allowing it to slide upward. The fragments were then brought together and fastened with thick silver wire, the wound properly dressed, and the patient recovered with a useful limb.

DR. G. G. DAVIS said that where swelling prevents the approximation of the upper and lower fragments, sometimes, by waiting a few days, the effusion will subside and the bone can then be held in place by adhesive plaster and bandages. The interposition of fibrous bands might delay healing, but would not produce markedly deleterious results, and their influence in producing such results had been much exaggerated, in his estimation. When the swelling does not go down promptly, he advocated tapping the joint and irrigating with normal salt solution. If necessary to hold fragments in apposition, he would use MALGAIGNE'S hooks, in preference to the passage of silk through the joint, a perilous procedure, as we know that it is impossible to disinfect the lower layers of the skin. If a stitch abscess may occur, then there is liability of the infection being carried by the silk into the joint. The good results obtained by DR. WHITE are attributable to the fact that, after the fragments are secured, early passive motion can be instituted. CHAMPIONNIERE aimed at the same result by the use of wire, and DR. DAVIS suggested a modification of MALGAIGNE'S hooks, having the same object in view.

PROFESSOR WHITE replied to his critics that he had not seen any results from what has been termed the old-fashioned treatment, which would at all compare with those he had obtained by the BARKER operation, and the same claim has been made by others who have performed it. Instead of the patients wearing apparatus for months or a year after the accident, his patients had returned to their work in two months without any form of splint or support whatever, and have perfect use of their limbs. He did not attach much importance to the question of bony union, as he was more interested in clinical results than in museum specimens. The shorter term of rest in bed and retention in the hospital, is a matter of great importance to a mechanic, and the ability to return to active industrial pursuits in a couple of months was to him the most striking result of this method of treatment.

The above summary of an able discussion of the

treatment of fractured patella contains some novel recommendations as to the management of these cases, but is especially interesting from the lucid explanation of the impossibility of surgeons coming to an agreement upon the method of managing fractured patella, considered as an abstraction; whereas when confronted with a given case, or cases illustrating simple and complicated fractures, there might be less difficulty in indicating the proper course to pursue. Not only are the pathologic conditions, or the results of traumatism to be considered, but the many modifying factors in the person or the environment of the subject must be allowed to have due weight, just as in other surgical problems, in which individual cases are to be decided upon their own merits. We agree with ASHURST that fractured patella in one man is not the same as fractured patella in another man, and hence there can be no absolute and invariable rule of procedure in the treatment.

#### WARFARE AMONG THE ADVERTISING "SPECIALISTS."

An advertiser of New York City, a "Doctor" H—, although he is a regular graduate in medicine, is a specialist "on the lung." After hunting the gulls of both country and city, he is now hunting one or more of his associates on the charges of forgery and larceny. The men who kept his accounts and correspondence, and who did the pharmacal work, set up in business for themselves and diverted to themselves quite a large share of the out-of-town receipts. In the course of this crooked work it became necessary to work off a fraudulent certificate of death. It was in the perpetration of this crime that the "doctor" got wind of the system of swindling of his associate "doctors."

That certificates of death should be received from the "doctor," and not from the other advertisers does not appear to have been explained, but it may be, for the moment, assumed that he is what the State Medical Society of New York has voted to harness itself with, namely, "a legal practitioner." Otherwise it will be difficult to explain how it came to pass that the "doctor" would venture to invite the law officers of the city to intervene on his account. However, they have so done, and the grand jury has found an indictment against the partner, named W—, for forgery in the second degree. His arrest followed and he was held in \$1,000 bail; an amount that he was unable to obtain. He was locked up in the Tombs. His lawyer has claimed for him that he has a medical diploma from a Venezuelan university.

The co-parcener in the fraud committed against the principal can not be found. This co-parcener was the one who had the knowledge of accounts, addresses of patients, etc., being the better able to aid "Dr." W— in establishing a "chronic depart-

ment" under the nose of his employer. Under this "department" they were able to fleece certain of the "doctor's" patients to the extent of \$25 for the first month and \$15 for the second month of pretended treatment. All of which shows the gullibility of mankind, especially of the sickly half thereof.

It does not speak very favorably for the medico-legal status of a community that permits such enterprises to bud, bloom and blossom forth so luxuriantly; and also permits the most flagrant end of the fraud to obtain quasi-support from the medical and legal authorities. Has the New York County Medical Society or Academy of Medicine any grounds for action against these people?

#### SMUGGLED PHENACETIN.

The firm of SCHIEFFELIN & Co., of New York City, has recently notified the Secretary of the Treasury of certain frauds upon the revenue. Drugs made in Germany, like phenacetin and sulfonal, have been brought into the country through Canada and sold at a figure 20 to 25 per centum lower than the regular prices of the authorized distributing agents in New York.

One druggist, hailing from Montreal, has been arrested and others in that city are on tenter-hooks in view of confessions said to have been made concerning the evasion of the revenue laws, which confessions are by two parlor-car porters, who have for years been on the Montreal "run" of two lines of railway. One porter was arrested in Boston.

The Treasury agents are said to be in possession of the names of numerous carriers and buyers of the low-priced drugs. The arrested Montreal druggist was put under bail of \$2,500. When his case was called May 28, he did not appear and his bail was put in default.

#### EUTHANASIAN HOME FOR NEW YORK CITY.

Those who have followed the specialization of charities in London have been aware of the establishment in that city of a home for the dying. It has something of an endowment and is limited to ten beds. It receives those who are hopelessly sick and believed to be near to death's door.

The *Evening Post* of New York has argued the advantages of such a home for that city, and it might be suggested if that paper is able to push the matter along to a successful end, that the name of the great poem of the late noble-minded editor of that paper—MR. WILLIAM CULLEN BRYANT—be chosen for the institution, as a part of its title; that is, it might be called the Thanatopsis Hospital, or Home. This would be better than the bald, rather repellant title, Home for the Dying.

There are doubtless many cases of given-up, non-medicable patients who would be vastly better off in

such a home, where trained nursing, if naught else, might be given to assuage the bitterness of a lingering death, than they could be in their own homes. Such an institution should be fully endowed, or not started at all.

#### THE ASSOCIATION.

One of our oldest and most valued members said the other day: "Why do you keep constantly drumming for new members? Is not our ASSOCIATION big enough?" Why, bless your soul, dear fellow, don't you know that nothing keeps spirit, dash and enterprise in our work, like the missionary work the members have done and are doing to lift our brave body into the place it should occupy as the foremost organization of medical men, at once the most powerful for good to humanity, and helpful to the profession itself. Of course it is a great ASSOCIATION, but it should be greater. Let us work, then, as we never worked before; to secure, first, the *largest* membership, and second, the *best* membership. Our ASSOCIATION to-day has only about one-third the membership of the British Medical Association. We *must* work, therefore, in generous rivalry, until we stand first, instead of second, and that is why we earnestly urge every member to put forth his own effort to increase the membership.

### CORRESPONDENCE.

#### The Kansas Hypnotism Case.

MILWAUKEE, WIS., May 31, 1895.

*To the Editor:*—Some time ago the secular press published a statement to the effect that the Supreme Court of Kansas had recognized a plea of hypnotism as a defense in a trial for homicide. Since then the statement has been reiterated, not only in a great many newspapers, but in some of the medical journals as well.

The statement is entirely untrue. The facts in the case are these: one Gray incited McDonald, an employe of the former, to kill a man named Patton, also an employe of Gray. McDonald was tried in the lower court and the defense sought to prove that Gray's influence over McDonald was exerted through hypnotic power; and the judge of the lower court allowed the introduction of expert testimony to establish this fact. McDonald was acquitted by the jury in the lower court; so his case did not reach the Supreme Court at all. Gray was tried in the same court and convicted. His case went to the Supreme Court on appeal and the judgment of the lower court was affirmed.

In the case of Gray, no testimony seems to have been introduced relative to the subject of hypnotism. Gray was convicted as an accessory. Judge Allen of the Supreme Court, wrote the opinion (May 2, *Pacific Reporter*, page 1050); and touched only four points, none of which had the remotest connection with hypnotism.

An examination of the testimony given in the lower court in the case of Gray shows that McDonald, with his wife, lived in the same house with Gray while Patton, the murdered man, lived on a distant part of the farm. Patton came over to Gray's house one morning and became involved in a quarrel with McDonald during which blows were ex-

changed. Patton then left, threatening McDonald with future punishment. After he was gone Gray told McDonald that Patton was a dangerous man, that he had killed seven men, and that he would "get some of us unless he were killed." He afterward took McDonald out into a field and instructed him in target shooting with a rifle. They then returned to the house and Gray cleaned the rifle, which belonged to him. He then took McDonald into an ambush, gave the rifle and some cartridges into his hands, and left him to wait for Patton who was expected to soon pass near to the place of McDonald's hiding. Gray returned to his house, but McDonald lay in wait several hours and when Patton was passing by shot and killed him.

The case is entirely devoid of any suspicion of hypnotic influence. It seems that McDonald was a man of very inferior intelligence and that fear for personal safety generated by the talk of Gray was his only motive in committing the deed. It is not possible to account for the verdict of the jury which acquitted McDonald, without knowing the characters of the parties involved and all the local prejudices which existed at the time of the trial.

JOHN MADDEN, M.D.

#### The Medical Profession and the Paris Exposition of 1900.

SOUTH BOSTON, MASS., May 29, 1895.

*To the Editor:*—There is a matter which it seems to me ought to interest medical men universally and to which I have seen no reference made as yet.

The Paris Exposition will be held in 1900. There, doubtless, medical science will be well represented. Would it not be desirable to have this representation systematized so as to enhance its value?

I believe no grander exhibit of things medical was ever made than that at the World's Fair in 1893, and yet the medical exhibit, as such, was a failure. I confidently assert that no doctor saw it all. No medical editor with comprehensive mind gave even a synopsis of what was there to interest the practitioner desirous of being abreast with the times.

I further assert that this failure to comprehend that exhibit was due to the defective manner of placing, or rather scattering the exhibit over the Fair grounds. To my personal knowledge there were medical exhibits in the Electrical Building, in the Anthropological Building and several separate exhibits in the Liberal Arts Building—in the spaces assigned to various nations, and for the most part difficult to find.

Why not have massed these separate exhibits together, so that the serried columns of facts, medical and surgical, should have irresistibly forced even the lay mind to comprehend the fact that medicine is a science and one of the greatest.

Anent the Paris Exposition of 1900, my proposition is this: *have all exhibits illustrative of medicine under one roof.* Doubtless this result can be attained if the attention and interest of the proper authorities can be secured—for France likes system, and simplicity is the essence of a good system.

Do you deem the matter of sufficient importance, Mr. Editor, for the representative medical journal of America to agitate?

Respectfully,

EDWARD A. TRACY, M.D.

#### Dr. Robert Koch and His Germ Theory of Cholera.

DUNKIRK, N. Y., June, 1895.

*To the Editor:*—Dr. Robert Koch has sought to explain the cause of certain diseases upon the hypothesis of the action of pathogenic germs, invisible to the human eye. Upon the

microscopic examination of the stools of cholera cases, he found different forms and kinds of germs, and among these was one of comma-shape, which he fancied was the cause of this disease. Through the process of "culture," and "experiment" upon the lower animals he asserts he has demonstrated that this germ is the actual cause of this disease. So confident was he that this newly discovered, comma-shaped object was the cause of cholera that for several years he continued to assert with the utmost assurance that the presence of these comma-shaped bacilli in the dejections of a person suspected of having this disease, constitutes positive evidence that the case is one of pure Asiatic cholera.

But this comma-shaped bacillus theory of cholera has proved a failure. These invisible comma-shaped germs are now found to be universal and harmless. They are found in the secretions of the mouth and throat of healthy persons, and in the common diarrheas of summer everywhere—they swarm in the intestines of the healthy and are observed in hardened fecal discharges as well. Dr. Koch to-day asserts that these bacilli are universally present. He even tells us that: "Water from whatever source frequently, not to say invariably, contains comma-shaped organisms."

Drs. Pettenkofer of Munich and Emmerich of Berlin, physicians of high distinction and experts in this disease, drank each a cubic centimeter of "culture broth," which contained these bacilli, without experiencing a single symptom characteristic of cholera, although the draught in each instance was followed by liquid stools swarming with these germs.

Dr. Koch has kept *au courant* with the foregoing facts, as well as others quite as significant, and, had he accepted the evidences which thus year after year have been forced upon him, his pernicious cholera germ theory with its most disastrous consequences in misleading mankind would have been unknown to-day.

HENRY RAYMOND ROGERS, M.D.

### Mississippi Valley Medical Association.

INDIANAPOLIS, May 27, 1895.

To the Editor:—Will you kindly mention in the next issue of our JOURNAL that the twenty-first annual meeting of the Mississippi Valley Medical Association will occur at Detroit, Mich., on Sept. 3, 4, 5 and 6, 1895, and that assurances have been received from the railroad companies that one fare for the round trip will be the rate? Wm. Pepper, M.D., LL.D., of Philadelphia, Pa., will read the Annual Address on Medicine on the evening of September 4. Dr. H. O. Walker, of Detroit, the Chairman of the Committee on Arrangements, says that the local profession of that city is prepared to entertain the society handsomely, and the indications thus far point to a very large and successful meeting.

Sincerely yours, W. N. WISHARD, M.D.

### Mortality of Physicians.

BINGHAMTON, N. Y., April 29, 1895.

To the Editor:—Can you refer me to any article or table published on the mortality of physicians?

Fraternally yours,

J. M. FARRINGTON, M.D.

ANSWER.—For complete list of works on the diseases and longevity of physicians see the Index Catalogue of the Library of the Surgeon-General's Office, U. S. A., vol. XI, p. 225. For the edification of our Danish scholars we mention the following: Gjennevnitslevalderen i den danske Lægestand i indevaerende Aarhundrede, M.C. F.C. Bladt, Ugesk. f. Læger. Kjobenh., 1879, 3. R., xxvii, 359, (which according to the "catalogue" means "concerning the duration of life of Danish physicians.")

### American Pediatric Society.

HOT SPRINGS, VA., May 29, 1895.

To the Editor:—Our Society has passed the following resolution:

Resolved, That in the opinion of the American Pediatric Society the evidence thus far produced regarding the effects of diphtheria antitoxin serum justifies its further and extensive trial.

Yours,

SAMUEL S. ADAMS, Secretary.

## BOOK NOTICES.

**Immunity, Protective Inoculations in Infectious Diseases, and Serum-Therapy.** By GEORGE M. STERNBERG, M.D., LL.D., Surgeon-General U.S. Army, ex-President American Public Health Association, Honorary Member of the Epidemiological Society of London, of the Royal Academy of Medicine at Rome, of the Academy of Medicine at Rio Janeiro, of the Société d'Hygiène, etc. One volume, 325 pages, octavo, bound in extra muslin, bevelled edges, uniform with the other volumes of the *Medical Practitioners' Library*. Price, \$2.50; in flexible morocco, \$3.25.

The uppermost topic of the day is that of serum-therapy and protective inoculations. We have here a book by America's foremost bacteriologist, in which the question is impartially reviewed from a bacteriologic standpoint. The book is divided in two parts, of which the first is given to natural and acquired immunity, and the second to protective inoculations and serum-therapy. The diseases anthrax, chicken cholera, cholera, diphtheria, foot-and-mouth disease, glanders, hog cholera, hog erysipelas, hydrophobia, influenza, influenza of horses, pleuropneumonia of cattle, pneumonia, rinderpest, smallpox, swine plague, streptococcus infection, symptomatic anthrax ("black leg"), tetanus, tuberculosis, typhoid fever and yellow fever are separately treated.

In regard to natural immunity, the author apparently makes good his claim to priority to the theory so well supported by Metschnikoff, of phagocytosis, but yields readily to the view that the leucocytes are probably not the principal agency in the destruction of bacteria in living tissues. Buchner's demonstration that the ammonium salts, (any alkali according to Van Fodor) will increase normal resistance to bacterial invasion, is not accepted by the author as conclusive on this point, but as showing that the germicidal constituent of the tissues, whatever it may be, is only soluble in an alkaline fluid.

In regard to Haffkin's protective inoculations the author says the results "indicate that these inoculations have a real value, but that immunity is not immediately established, and consequently that during an epidemic a certain number of fatal cases may be expected among the inoculated as well as among the non-inoculated." The author regards the evidence in regard to immunity from smallpox, as probably due to the presence of an antitoxin in the blood of the immune individual. He cites his own experiments made at Brooklyn, and refers to Kinyoun's cases of injection of blood serum from an immune calf. As would seem natural, the author having devoted much of his life to the study of yellow fever, he again takes up the Domingoes Freire inoculations for yellow fever, those of Finlay, and resuscitates the old experiments of Wm. L. de Humboldt made in 1854 and 1855. We note a clerical error in the translation of the letter of Dr. de Humboldt to General Concha; in the original the number of cases inoculated by him in Vera Cruz was given as 1,438, not 1,458 as stated, (see Manzini, p. 2.) The bibliography at the conclusion of each chapter is valuable and complete.

We welcome the book to our table, not only as a sound and safe counsel on the theories of the day, but as an instructive and useful summary of the literature of the subject.

**Saint Bartholomew's Hospital Report.** Edited by SAMUEL WEST, M.D., and W. J. WALSHAM, M.D. Vol. xxx. London: Smith, Elder & Co. 1894.

The editors of these reports usually succeed in making an interesting report, but they have been remarkably successful this time. In addition to the routine reports of matters pertaining exclusively to the hospital there are twenty-six separate articles viz: I, Aneurysm of the ascending part of the Arch of the Aorta, taking the natural position of the Heart, by Samuel Gee; II, Primary Cancer of Pancreas by W. P. Herringham, M.D.; III, Chloroform Anesthesia by Rich-

ard Gill; iv, Symphysiotomy by C. Hubert Roberts, M.D.; v, on the Association of Cardiac Malformations, with other Congenital Defects, by Archibald E. Garrod, M.D.; vii, Treatment of Senile Gangrene by R. Cozzens Bailey, M.S.; viii, The Great Omentum, by W. McAdam Eccles; x, Dietetic Value of Food Stuffs prepared by Plants, Rev. George Henslow, M.A., F.L.S.; xii, History of Diphtheritic Paralysis, by J. J. Macan, M.D.; xiii, Diagnosis of Diphtheria; xiv, Diphtheria Immunity of Puerperal Women, by James Adams, M.D.; xv, On the Gradations of Health and Disease, by Harry Campbell, M.D.; xvi, Life and Works of Percival Pott, (the Wix prize essay for 1894) by Thomas J. Horder, B.Sc.; xix, Treatment of Nævus by Electrolysis; xxiii, A Second Year's Surgery at Saint Bartholomew's Hospital, by Henry T. Butlin; xxiv, Chronic Purulent Catarrh of the Accessory Nasal Sinuses, by W. J. Walsham; xxvi, Blood Casts in Phthisis, by Samuel West, M.D., and reports of interesting cases, by E. P. Paton, Edgar Willett, H. M. Bowman, G. C. Garratt, D. H. Goodsell and Thomas Smith, and "Notes," by T. Lauder Brunton, M.D., F.R.S., and W. J. Horne, M.D.

The article of Mr. Butlin is particularly interesting, as "in the last volume of the reports" he gave "an account of a year's surgery, during which" he "made the attempt to dispense with some of the rigid details of the antiseptic method, and showed how suppuration followed. . . too frequently." This year the strictest precautions were observed and in consequence, the results were very much improved. We will quote a paragraph from Mr. Butlin which to our mind is well worthy of reproduction, as a caution to young dressers and assistants, not to overdo the matter of scrubbing:

"Let me say that the active preparation of the skin which has been described is only suitable for the skin of hospital patients. It is not only too vigorous, but wholly unnecessary for patients outside the hospital. Indeed, in some of the hospital patients, a smart eruption was not infrequently produced which was sometimes pustular. To say nothing of the discomfort which is produced by such a condition of the skin, I am not at all sure that it is more desirable to operate through the skin which is the seat of a pustular eruption, than it is to operate through skin which has been theoretically imperfectly prepared." While we are not prepared to go as far as Mr. Butlin, there is no doubt that rough scrubbing is very frequently too vigorous.

A great many of the articles have a permanent value, and the volume well deserves recognition as one containing very much of enduring value.

**Pathology and Treatment of Diseases of the Skin, for Practitioners and Students.** By DR. MORIZ KAPOSI, Professor of Dermatology and Syphilis, and chief of the clinic and division for skin diseases in the Vienna University. With 84 illustrations. Translation of the last German edition under the supervision of DR. JAMES C. JOHNSTON. Pp. 684. New York: Wm. Wood & Company. 1895.

No one can speak with more authority than Kaposi on any subject connected with dermatology, and in the opening chapter the author points out that the study of skin diseases means the careful study of pathologic processes, which are nearly the same in all parts of the body, and the study of these pathologic changes on the skin furnish a very convenient means of comparison with analogous processes in internal organs.

There is a scholarly chapter on the history of the development of dermatology from the ancient to the most recent times, and then follow the fifty-three lectures which form the book.

In speaking of lupus, Professor Kaposi states that in Austria, lupus constitutes 66 per cent. of all skin diseases. The removal of lupus, says our author, "can only be effected by mechanical or caustic interference. The most rational and

simple mode would be that of excision of the entire process, followed immediately by transplantation according to Thiersch's method or the ordinary methods of plastic surgery. Unfortunately, the localization and extent of the foci are poorly adapted to this plan of treatment. In addition, experience shows that relapses may occur even in the transplanted flaps. Nevertheless this method merits more frequent use. It should be kept in mind, however, that a flat thin cicatrix of the nose, eyelids and face, obtained by prolonged treatment, causes less deformity than a plastic operation which is not brilliantly successful."

**La Methode Brown-Sequard, Traite D'Histotherapie.** *La thérapeutique des Tissus, Compendium des Médications par les extraits d'organes animaux, par le Dr. M. BRA.* OUVRAGE précédé de lettres et préfaces de MM. les Professeurs CONSTANTIN PAUL, MENDEL EWALD, BAUNS, EMMINGHAUS et BYROM BRAMWELL, accompagné de 72 gravures. Paper. 8vo., pp. 624. Paris: J. Rothschild. 1895.

It is now six years since Brown-Séquard startled the world by a communication to the Société de Biologie in which he set forth the surprising results of subcutaneous injection of testicular fluid, and since that time animal tissue extracts have been gradually increasing in use. The author has succeeded in this volume in bringing together a mass of facts collected of the results of the new therapy, which Ewald has named "organotherapy," "histotherapy," by its founder, or "cyto-therapy" as proposed by Gley. There are thirteen chapters, the first on Organic Liquids in General; ii, Special Organic Liquids. In these chapters, the reagents used in the preparation, and the instruments are described, doses, frequency and general methods are given. The remaining chapters discuss particular extracts, their physiologic action, and therapeutic results. The whole is written from the standpoint of an enthusiast. The chapter on the use of the thyroid extract is very interesting, and its use seems to have been followed by more positive results than in most of the other preparations. The work is a complete summary of the literature of the subject.

**Weekly Abstract of Sanitary Reports.** Issued by the supervising Surgeon-General, under the National Quarantine Act of April 29, 1878, and the Act of Feb. 15, 1893. Vol. VIII., (Nos. 1 to 52.) Washington: Government Printing Office. 1894.

This bulky volume of 1,300 pages consists of the current numbers of the weekly abstracts for the year 1894 with a full index, bound in one volume for convenient reference. It will be found very useful, when comparing mortality tables or the various questions in epidemiology that may arise from time to time.

## PUBLIC HEALTH.

**Compulsory Notification of Infectious Diseases in Constantinople.**—An Imperial irade has rendered obligatory in Constantinople the notification of the existence of cholera, variola, varicella, measles, scarlatina, dysentery, diphtheria, typhoid and typhus fevers, whooping cough and phthisis. Doctors neglecting this notification will be fined.<sup>1</sup>

**California State Quarantine Station.**—Dr. J. H. Davisson, President of the California State Board of Health, announces that the board has made arrangements, which are being carried out as rapidly as official procedure will permit, for the establishment of a State quarantine station at Cabazon, which place is on elevated ground, not far west of Indio. A quarter-section of ground is being purchased for the station, and it is the expectation to place there the necessary equipment for the comfort of passengers who may be detained in order to prevent the invasion of disease. Dr. Davisson says the station is not intended for the purpose of establishing a quarantine against consumption, as has been reported. It

<sup>1</sup> La Semaine Médicale. April 20, 1895.

is intended rather to be used to guard against invasion by smallpox, yellow fever, cholera and similar diseases.

**Chewing-Gum is not Food.**—The great American craze of gum-chewing has gotten over to England and into the English courts. The *Public Health* for May, recounts a hearing before a Divisional Court, two justices sitting, the outcome of which was a decision that chewing-gum, or chewing-wax is not an article of food under the Food and Drugs Act of 1875. The price over there appears to be one half-penny a stick, and apothecaries who keep the article on sale have a label prepared which states that the article is, "For chewing only, not to be eaten." The effort to "stamp out" the use of chewing-gum in this instance was a complete failure.

**Washington Navy Yard Sanitation.**—In the recent report of the Navy Medical Board, appointed by Secretary Herbert to investigate the sanitary condition of the Navy Yard at Washington, it is pointed out that owing to the defective condition of certain sewers in that vicinity and the proximity of "the flats," from which during the prevalence of southerly or westerly winds, miasmatic effluvia are wafted over to the Yard, there is more or less malaria there and in its neighborhood. While the Commissioners of the District have no jurisdiction over "the flats," at least so far as the improvement of them is concerned, they have full control over the sewers and can do much to remedy the unsanitary conditions, and how this remedy may be applied is also suggested in the report. The Board says that even after all is done that the Commissioners can do, complete exemption from miasmatic influences will not be secured until "the flats" on the opposite shore of the river have been entirely reclaimed.

**Alcoholism in Belgium and Algeria.**—While the number of saloons and retail liquor shops in Belgium has decreased 38,000 in the last five years, the results obtained toward lessening alcoholism are not deemed satisfactory by the Government. A commission has been appointed to inquire into the ravages of alcoholism in that country and to study the remedies for the situation. According to Dr. Rouby, with a few exceptions the Arabs in Algeria drink nothing but water; the European colonists drink all the absinthe and alcohol. The number of insane sent from Algeria to the asylum at Aix bears out this assertion. From January 1 to August 1, 1894, two Arabs and fourteen colonists suffering from alcoholic insanity were received out of a population of 1,459,000—1,258,500 of whom are Arabs and 133,000 French. Thus with a population nine times less the French colonists furnish seven times more alcoholic insane. Rouby estimates that the proportion of non-insane alcoholics is 2,000 Arabs to 44,000 colonists for the whole colony. He thinks this furnishes food for serious thought, and that the conquerors are succumbing to alcohol faster than to firearms.<sup>1</sup>

**Deafness among School Children.**—The fact that myopia is frequent among school children is well known. It is not so well known that impaired hearing is also frequently met with. The children thus affected are often accused of being lazy and inattentive, when in reality their ears are at fault. Helot shows that these cases are quite common, are easily recognized, are generally incurable and when cured a large number of children are transformed, so to speak, both from a physical and a moral standpoint. According to Weil of Stuttgart, the proportion of school children with impaired hearing is 35 per cent.; according to Moure of Bordeaux, 17 per cent. Helot agrees with Gellé and other aurists that the proportion is almost 25 per cent. or one-fourth. All the children in a class should be carefully examined and these semi-deaf pupils will always be found among the "poor scholars." The cause of the infirmity is to be sought for—naso-pharyngeal catarrh following measles, scarlatina, whooping-cough, adenoid vegetations, hypertrophied tonsils etc.—and normal conditions are to be restored by appropriate treatment.<sup>2</sup>

**An International Sero-Therapeutic Institute.**—In an interview between Professor Rummo, editor of the Naples medical daily journal, *Riforma Medica*, and Professors Ferrannini and Behring, the famous German expressed the wish, in view of the present uncertainty as to the strength and purity of antitoxic serums prepared in different laboratories and used in different countries, that there should be an International Sero-Therapeutic Institute established, to which all serum manufactured throughout the world should be sent and tested by an international committee appointed for the purpose. A standard of strength and quality should be decided on, and the committee should withhold its sanction from any serum which failed to come up to the standard. This should apply not only to the diphtheria antitoxin, but to all kinds of serum intended for therapeutic use. In fact, there should be a control of serum of exactly the same kind as exists in all civilized countries for weights and measure; only it must be international. As Malcolm Morris says in the *Practitioner* for May, this would eliminate the element of *chaurinisme*, on which Professor Behring lays great stress as a disturbing influence in scientific matters. Moreover, it would secure the uniformity in medication which is a necessary condition for the formation of an accurate judgment as to the therapeutic value of the remedy. Professor Behring says that all the scientific authorities to whom he has spoken on this subject, and particularly M. Roux, are in agreement with him as to the desirability of such an institute as he has in mind. He is indifferent what country may be chosen for the purpose, provided the thing is done. Professor Ferrannini suggests Switzerland as at once central and not likely to excite national jealousies.

**Canine Diphtheria.**—It has been hitherto believed that of the lower animals only cows, guinea-pigs, cats and some of the *ares* were capable of communicating diphtheria to the human family. But now it is reported that the health authorities of Akron, Ohio, have traced thirty cases and three deaths of this disease to a dog belonging to a milkman along whose route the cases occurred. Investigation of the milkman's premises disclosed, near the place where his milk cans were left over night, a dog-kennel, the occupant of which showed every symptom of diphtheria. Physicians said there was no doubt the dog had the disease. It had been sick three weeks. While the doctors went to the city to obtain tubes to take a bacteriologic culture of the substance from the animal's throat the dog escaped and has not since been seen. The cans to which the dog had access and the buildings were thoroughly disinfected and since then no new cases have developed. The dog has not yet been discovered and there is much alarm felt in consequence. President Sargent of the Sanitary Board is supported by leading physicians in his belief that the dog was the cause of the spread of the disease and is still disseminating the germs. A close watch is being kept for the animal. It is to be hoped in the interest of the etiology of diphtheria, that this dog may be found; he should be an historic animal. It should be mentioned, by the way, that a child suffering with the disease was discovered on the first inspection of the dairyman's farm, but this fact is relegated to proper insignificance by the statements that the farm was "in a cleanly condition, the peddler had not been near the little one and the milk he sold was secured at a distant farm." *Ergo*, it must have been the dog.

**The Archbishop of Dublin and Vaccination.**—Shall the clergy use their influence over their flocks to favor vaccination and thus prolong the lives of the latter? The *Independent* says, yes, and avers that a church magnate, no matter how exalted his position, can be engaged in no better business than keeping his sheep away from the variolous wolf. That paper shows that the French clergy did a great deal to popularize the use of vaccine in the early years of this century, and Jenner is reported to have himself taken pains to teach English clergymen how to introduce the lymph. The *Independent* adds the following: "Archbishop Walsh of Dublin,

### THE CONSERVATIVE USE OF THE STOMACH TUBE IN THE TREATMENT OF GASTRIC DISEASES.

Read by title in the Section on Practice of Medicine at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY J. M. G. CARTER, M.D. Sc.D., Ph.D.

PROFESSOR PREVENTIVE AND CLINICAL MEDICINE, COLLEGE OF PHYSICIANS  
AND SURGEONS OF CHICAGO; FELLOW OF THE AMERICAN ACADEMY  
OF MEDICINE, ETC.  
WAUKEGAN, ILL.

The use of the stomach tube in the treatment of gastric affections has become so common in certain localities that it is necessary to call attention now and then to the dangers, as well as to the advantages of its use, and to study its scientific application.

Since Kussmaul urged the advantages of the stomach tube in 1867, the profession has given more or less thought to it; Leube in 1874 recommended the tube for diagnostic purposes, and in 1875 Ewald used the soft rubber tube for washing out the stomach. During the last twenty years it has gained in favor, and diseases of the stomach have been so thoroughly investigated by means of this instrument and the chemic analysis of the stomach contents, that a new specialty has been placed in the medical field.

A word of caution needs to be uttered to prevent the popularity which this method has attained from carrying its use too far. No more cases occur now which need the tube than did before the discovery of its value rendered its use so common. It requires skill and patience to know when it should not be used and to wait for the slower processes of other methods of treatment.

It is well, then, to mention briefly some objections to, and dangers accompanying its use. Some degree of alarm is occasionally felt at finding portions of mucous membrane attached to the tube when it is withdrawn from the stomach. Especially is this the case with stiff instruments. It may occur also with the soft tubes. Where the patient's mucous membranes are thin and easily irritated, and where the epithelium is more readily removed than seems normal, I dislike to use the tube. In such cases abrasions are likely to occur, and although there is a tendency to rapid healing under such circumstances, the possibility remains that some cases may not heal and the traumatism may lead to ulcer of the stomach. The possibility of such an occurrence should suggest a careful investigation of the mucous membrane before introduction of the tube. In aphthous and other inflammatory states it is ordinarily not advisable to use the tube. Another danger is that perforation of the esophageal or gastric wall sometimes occurs. The possibility of this accident should be remembered in stenosis of the cardia or esopha-

gus, in ulcer of the stomach and in the later stages of gastric cancer. This accident has occurred in very skillful hands and is not to be lightly viewed. Such cases have been reported by Abercrombie, Frey, Richs and others. I should consider the stomach tube contra-indicated in stenosis due to pressure of aneurysm or abscess, and in cases accompanied by degeneration of the tissues above the stricture—a matter, however, which could not be easily discovered before death. In ulcer and the later stages of cancer of the stomach, the danger of perforation is sufficient to contra-indicate the use of the tube except in rare instances. An objection to the use of the tube in inflammation or congestion, in ulcer and in altered conditions of the mucous membrane is the fear, even the probability, of causing hemorrhage. These hemorrhages are not always manifested as a sudden hematemesis but may, by causing an abrasion of the mucous membrane or rupturing a small vessel, produce an oozing or slow hemorrhage, sometimes shown only by darkened or blood-stained stools. However, an alarmingly profuse hematemesis may occur and the possibility of this accident should be eliminated or reduced to the minimum by extreme caution in such cases.

The fact that syncope and death have resulted from the use of the stomach tube is a matter of considerable interest and great importance. The varying pressure upon the great abdominal plexuses of the sympathetic, produced by filling and emptying the stomach with the tube is believed by Fenwick to be the cause of this accident. The indiscriminate washing out of the stomach and filling the stomach with excessive quantities of water are to be discouraged.

Besides the evil results which may occur from pressure upon the sympathetic plexuses, it is undoubtedly true that the mere irritation of the mucous membrane in the stomach by the presence of the tube may produce fainting or syncopic attacks, as also occurs occasionally when food is introduced into the stomach. These cases seem to occur under circumstances where the irritation would ordinarily produce vomiting, but some idiosyncrasy causes the syncope instead of nausea, or perhaps both sensations may be experienced.

Spasm and tetany are sometimes met with and the latter may prove fatal. Manges gives 72 per cent. as the mortality in cases of tetany. Although few cases have been reported as compared with the great number of times the tube has been used, still precaution is urged, as we do not know in advance what patient may die from this complication. The spasm of the throat is very common and in many cases requires the use of cocaine. Spasm in children may prevent the use of the tube except under chloroform or ether. Another objection to the use of the tube, which has been considered by some even more serious than those already mentioned, is the removal of the

natural secretions by lavage. The habitual washing out of the stomach when considered from this point of view only, undoubtedly is to be discouraged. The withdrawing from the body's nourishment of the chyme which the stomach labors so hard to manufacture is not to be considered lightly; but if the digestive and absorptive powers of the viscus are impaired it can not be known that undigested food does not remain in the stomach until it acts as a foreign body. If relief is afforded the patient by the use of lavage it may be accepted usually as evidence that good has been accomplished. Still it must follow that no general treatment by lavage should be adopted until careful investigation has shown that the benefits to be derived outweigh the risks assumed.

Again, when lavage has accomplished its work it should be stopped. Further use may prove to be a positive evil. I know a case where a young lady was advised to use the stomach tube for nervous or functional dyspepsia. She submitted to the treatment by a young physician who was very enthusiastic in his work. The patient improved for a time. At this point a conservative physician would have stopped the treatment. The lavage was persistently continued for months, however, the case growing worse; and after a year of such treatment the too submissive patient was not so well as she was when the lavage was begun. Such instances of indiscretion in the use of any remedial agent, while suggesting caution, do not militate against the value of the measure when properly used.

I should advise the use of the tube for the purpose of lavage or washing out the stomach for the following six objects: 1, to remove undigested food and foreign matters; 2, to cleanse the mucous membrane for the action of medicines; 3, to check hemorrhage; 4, to give antiseptic douchings; 5, for sedative purposes; 6, for general tonic effects upon the stomach, mucous membrane and paretics.

1. The removal of undigested foods may become necessary in indigestion, functional dyspepsia, dilatation, cancer and pyloric stenosis. In such cases nothing can be done until the stomach has been relieved of the offending matter. Frequently in some of these cases vomiting can not easily be induced, and in others it is not to be encouraged. It is a common experience that no treatment gives such complete temporary relief in functional dyspepsia, dilatation, cancer and stenosis as lavage. This removes the undigested remnants of food, fermentative and putrefactive products, and exercises a beneficent tonic influence upon the gastric mucous membrane.

2. In atrophy, chronic gastritis and also in functional dyspepsia, as in other neuroses, washing the tenacious mucus from the membrane gives a surface by which medicines are more readily absorbed. There is no doubt that tardy recoveries or entire failures in the treatment of some neuroses, including atonic or nervous dyspepsia, are due in part to the failure of the gastric mucous membrane to absorb the medicines prescribed. This occurs often where the absorptive function is not materially impaired. Such cases can be explained by supposing that the tenacious mucus on the mucous membrane interferes with the process of absorption. The removal of this mucus will facilitate the action of the medicines which are given.

3. The application of cold is a common method of

controlling hemorrhage. Ice-cold water can be applied to the mucous membrane of the stomach in hematemesis in two ways. First, the patient may be required to drink ice water and swallow bits of ice. The quantity which can be thus used is limited. Second, it frequently happens that hemorrhages occur in ulcer and other pathologic conditions under circumstances which do not forbid the use of the stomach tube and where a prolonged application of cold to the gastric surface is desirable. In such conditions one is justified in applying a continuous douching by withdrawing the water after it has been in the stomach four or five minutes and re-introducing a supply of ice-cold water to be again withdrawn in the same manner. This process may be continued as long as necessary, if no untoward symptoms arise from the prolonged use of cold. In ulcer, cancer, and rupture of vessels of considerable size, danger may attend the expression method of emptying the stomach; hence it is wise to use an aspirator or exhausting bulb or syringe to remove the water.

4. One of the most simple and advantageous uses of the tube is for the purpose of removing the products of fermentation and putrefaction. In all diseases where fermentation occurs, as in functional dyspepsia, certain other neuroses, dilatation, chronic gastritis and cancer of the stomach, the gases and other abnormal products of faulty digestion act as irritants, and nothing relieves the patient so quickly and completely as lavage. In many of these cases, especially nervous dyspepsia and gastrectasis, and often in chronic gastritis, lavage not only serves to give temporary relief, but is also an excellent therapeutic agent in accomplishing a permanent cure.

5. Perhaps no class of diseases of the stomach is so generally benefited by lavage as the neuroses. Functional dyspepsia has already been mentioned. Gastralgia, nervous eructation, hyper-secretion, the various conditions accompanying neurasthenia and nervous vomiting are frequently thus relieved, the depraved condition (if one exists) which allows these states to arise removed, and a gentle tonic influence imparted to the gastric mucous membrane which is spread until it helps to remove the cause of the neurosis. The impression made upon the general nervous system, the quick response of the sympathetic system, the increase in the circulation and consequently the improved general metabolism are, without doubt some of the most important effects of washing out the stomach in these cases. The readiest means of relieving obstinate hiccough, heartburn and other symptoms of gastric irritation may often be found in the use of lavage. No one who has had large experience in such cases can doubt the beneficent influences of lavage. Nevertheless, there are some neurotics who can not submit to the lavage treatment on account of syncopic or other distressing symptoms.

6. It can not be doubted that cold or tepid bathing and sometimes hot bathing produces general tonic effects. Similar effects are often observed in the lavage treatment of the stomach—bathing or washing that viscus. In atonic conditions of the muscular coat of the stomach, in anemic conditions of the mucous membrane and in deficient gastric secretion, there are few remedial agents which will produce better results than systematic lavage. Auto-lavage, or the use of the tube by the patient is not to be encouraged, except in the few cases where definite in-

structions with proper cautions and restrictions will be observed.

A review of the foregoing study of our subject reminds us that while the field for lavage is large and its position as a therapeutic measure established, it requires skill and care to use it always for good and not for evil. There are many conditions, idiosyncrasies and circumstances which will forbid its use. Some of these can be overcome, some can not. Conservatism should mark the physician's course here, as in most departments of medical practice.

## THE EFFECT OF INHALATION OF OXYGEN UPON THE HEMOGLOBIN.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY GEORGE J. PRESTON, M.D.

PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE NERVOUS SYSTEM  
COLLEGE OF PHYSICIANS AND SURGEONS,  
BALTIMORE, MD.

Ever since the discovery of oxygen by Priestley in 1774, it has been used as a therapeutic agent. In fact, Priestley himself made a number of experiments upon animals with the gas, thus preparing the way for experiments upon the human subject. A few years after his discovery, Lavoisier and Spalanzani demonstrated the relationship of oxygen to atmospheric air, and showed in a rough way the changes it produced in the blood. These experiments were more physiological than therapeutical, but not long after this date, Caillens in 1783 employed oxygen therapeutically. Jurine of Geneva, and Chaptal of Montpellier, followed with reports of cases of phthisis benefited by its use. The report of Fucroy to the French Academy was very extreme, making as it did absurd claims for oxygen in the treatment of numerous diseases. Beddoes in 1789 made a number of important observations upon the physiologic action of oxygen, and also employed it in practice. In conjunction with Sir Humphrey Davy and James Watt he established an institution for the treatment of disease by oxygen, an account of which may be seen in an extremely interesting paper on its therapeutic use by Dr. A. H. Smith in the *New York Medical Journal*, April, 1870. Gardner in the *American Journal of Medical Sciences*, 1844, makes the remarkable statement that, "by the use of peroxid of nitrogen, or by rapid breathing, an increased quantity of oxygen enters, and as it can not be expelled as an element it acts upon more atoms of fibrin." Richardson made a number of experiments upon animals, and concludes that "the blood does not take up more oxygen unless more CO<sub>2</sub> is given off." (*Lancet*, 1878.)

The above citations taken from the literature of the century following the discovery of oxygen, will give some idea of the way the profession regarded the subject. The literature is quite considerable but of little real value, since the rather crude experiments proved little, and the clinical experience related proved entirely too much. The experiments of Lavoisier and Spalanzani referred to above, showed the effect of oxygen upon the blood, although the fact that blood exposed to the air changed color was known long before this time, as early as 1665. Davy then extracted oxygen from blood; Regnault and Reiset and also Liebig announced that animals used the same amount of oxygen when breathing an atmos-

phere composed of that gas alone as when they breathed ordinary air. (McKendric.) Liebig claimed that the gases were not merely dissolved in the blood, but existed in a state of loose chemic combination. Funke, Hoppe-Seyler, Schmidt, Stokes and others between the years 1853 and 1864 carefully worked out the nature and function of hemoglobin.

The history of the experiment of placing animals in an atmosphere of pure oxygen is an interesting one to physiologists, serving as a valuable object lesson. For many decades after the discovery of Priestley it was held that an animal could not live in this pure element. Then it was discovered that by providing for the absorption of the expired CO<sub>2</sub> the life of the animal could be indefinitely prolonged. In regard to the number of respirations, my experiments showed that for the first few minutes there was a great rise, then a fall to about half the normal number. In the human subject the inhalation of pure oxygen seems to have little effect upon the pulse or arterial tension, but diminishes the number of respirations.

Admitting the fact that inhalations of pure oxygen under normal temperature and pressure, cause merely a diminution in the number of respirations a very practical question arises, namely, whether in the inspiration of pure oxygen the blood becomes more highly oxygenated than it does when ordinary air is breathed. The early observers fixed hardly any limit to the absorption of oxygen, believing it to be merely dissolved in the fluid as a whole. Then it was shown that the hemoglobin of the red corpuscle played a very important part, appropriating the oxygen from the plasma. As a matter of fact the serum is capable of absorbing little if any more of this element than of distilled water. The relationship which hemoglobin bears to the red corpuscle is still somewhat *sub judice*; we simply know that the combination of oxygen with hemoglobin is a very loose one, subject to certain laws of pressure and temperature, and that disassociation may be very easily brought about without disturbing the molecule of hemoglobin. (Foster.) The old observers thought that by the inhalation of pure oxygen a condition of what they termed "super saturation" of the blood was obtained. More exact observation showed this view to be untenable. Under pressure it is possible to make the serum take up more oxygen just as distilled water will do under like conditions. The quantity taken up by the hemoglobin of the red corpuscles is fixed, or nearly so. Experiments upon a solution of hemoglobin show that if a sufficient quantity of oxygen be present, each gram of the solution will take up 1.59 c. c. If there is an insufficient quantity present the hemoglobin will not be completely satisfied, or, to quote Foster: "We may perhaps say that a part only of the hemoglobin gets its allowance of oxygen, while the remainder continues reduced." Or it may very well be that while breathing ordinary air, a certain proportion of the red corpuscles pass through the pulmonary capillaries with their hemoglobin unsatisfied, or only partially satisfied with oxygen. The following experiments bear upon this point. The animals were placed under a glass jar which was first filled with pure oxygen which had been washed several times and a stream of the gas was allowed to pass into the jar from a cylinder. A sufficient quantity of caustic potash was kept in the jar to absorb all the CO<sub>2</sub>. The hemoglobin was measured by the hemo-

globinometer of Fleischl before and after the experiments.

Experiment 1. White rabbit; hemoglobin 58; respirations 100. Was kept in the oxygen for five minutes, and at the end of this time the number of respirations had gone up to 200 a minute and there was no change in the per cent. of hemoglobin.

Experiment 2. Black rabbit; hemoglobin 52; respirations 100. Was kept in oxygen for fifteen minutes. The number of respirations fell to 80 and the per cent. of hemoglobin rose to 80.

Experiment 3. White rabbit; was kept in oxygen for thirty minutes and respirations dropped from 100 to 60, and hemoglobin rose from 58 to 62.

Experiment 4. Black rabbit; one hour in the oxygen; respirations dropped from 100 to 35, and hemoglobin rose from 52 to 67.

Experiment 5. White rabbit; thirty minutes in oxygen; respirations dropped from 120 to 56 and hemoglobin rose from 55 to 62.

Experiment 6. White rabbit; one hour in oxygen; respirations dropped only 10, and there was no change in the hemoglobin. It was ascertained afterward that the oxygen in the cylinder was exhausted toward the close of the experiment.

Experiment 7. White rat; respiration 200; hemoglobin 94. Kept in oxygen thirty minutes. Respiration dropped to 100; hemoglobin rose to 97.

Of the seven experiments, there were only two that did not show diminution in the number of respirations and rise in the percentage of hemoglobin. Of the two failures Case 1 was not kept in the oxygen long enough, as later experiments proved, and the other, Case 6, through the exhaustion of oxygen in the cylinder was breathing practically atmospheric air toward the close of the experiment.

Experiment 8. Small dog. Oxygen was injected into the rectum for forty minutes. Respirations fell from 24 to 10; hemoglobin rose from 82 to 84.

In addition to the above experiments on animals, the following observations were made on four healthy men:

Experiment 9. Mr. C., weight 140 pounds; inhaled oxygen for seven minutes; hemoglobin estimated before inhalation 82; after 92.

Experiment 10. Mr. B., weight 160; time of inhalation five minutes; hemoglobin, before 78; after 87.

Experiment 11. Mr. C., weight 150; time of inhalation six minutes; hemoglobin estimated before inhalation 76; after 83.

Experiment 12. Dr. P., weight 190; inhaled oxygen five minutes; hemoglobin estimated before inhalation 80; after 95.

There were no special symptoms attending the inhalation of oxygen except a certain lessening of the desire to breathe. There was not present the exhilaration and quickened pulse which has been described. This agrees with the observations made by Kerr, (*Lancet*, 1893). While one naturally hesitates to draw conclusions from so small a number of experiments, still it would seem reasonable that the inhalation of pure oxygen raises decidedly the percentage of hemoglobin in the blood. In all probability this is brought about, not by increasing the oxygen in the plasma, but by the fact that an excess of oxygen being present, all the hemoglobin is satisfied; or, to put it another way, fewer of the red corpuscles pass through the pulmonary capillaries, without obtaining their complement of oxygen.

While making these experiments it occurred to me that something might be learned from the study of the blood during and after the use of anesthetics. The first case examined showed a decrease of hemoglobin from 80 to 68; the estimations were made before the subject was put under chloroform and again after he had been under the influence of the anesthetic for fifteen minutes. Shortly after beginning this series of experiments I saw the very interesting paper by J. C. DaCosta, published in the *Philadelphia Medical News*, March 2, 1895. This observer demonstrated the marked reduction of hemoglobin during etherization, and also showed that this was not due to any diminution in the number of the red corpuscles. These experiments of DaCosta's taken together with my own, would go very far, it seems to me, toward proving the truth of the supposition stated in the first part of this paper, that in ordinary respiration a certain proportion of the red corpuscles were not completely satisfied with oxygen, or that in their passage through the pulmonary capillaries many of the corpuscles got through without having their reduced hemoglobin acted upon by oxygen.

The subject of the therapeutic use of oxygen, if any one will glance over the literature, has been treated in a thoroughly empirical manner. Almost every known disease has been cured by its use, if we can believe the glowing accounts of enthusiastic advocates. Moreover it has been so largely used by quacks, and so actively advertised by nostrum vendors, that the profession have naturally been deterred from its use. The investigation and the experiments related above were undertaken to see whether or not there was any scientific basis for the many claims made for the therapeutic use of oxygen. Although these experiments have been few, and not very exact, still enough has been done to show that the percentage of hemoglobin in the blood can be largely increased by the inhalation of pure oxygen. This method should have a full and scientific trial in pneumonia, acute bronchitis, pulmonary emphysema, pulmonary tuberculosis, and diseases obstructing the air passages. Again it might give good results in the treatment of certain forms of anemia. Its most brilliant future probably lies in its use by rectal injections. Kellogg and others have made some limited experiments with this method of introduction, but it needs further trial. Among those who have recorded clinical observations in the use of oxygen in various diseases are Gardner (*American Journal of Medical Sciences*, 1844); Birch (*Lancet*, 1857); Richardson (*Lancet*, 1878); Professor Cabell (*Virginia Medical Monthly*, 1874); Oppenheim (*Deutsch. Med. Woch.*, 1876); Hayem (*Gaz. des Hop.*); Gray (*Virginia Medical Monthly*, 1874); Wallian (*N.Y. Med. Rec.*, 1883-84-85); (*Med. News*, 1890); Neech (*British Medical Journal*, 1892); Kerr (*Lancet*, 1893), and many others. For the full description of the methods of using oxygen therapeutically, reference is made to the interesting paper of Aulde in the *JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Dec 6, 1890. These preliminary notes on the use of oxygen are offered in the hope that the profession may be induced to make further and more careful use of an agent which theoretically, at least, should prove valuable.

## LEAD ENCEPHALOPATHY, WITH A REPORT OF A CASE.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY ALBERT E. ROUSSEL, M.D.

ADJUNCT PROFESSOR OF PRACTICE AND OF CLINICAL MEDICINE, MEDICO-CHIRURGICAL COLLEGE, ETC., PHILADELPHIA.

R. H., age 35 years, an artist by profession, first consulted me March 3, 1890. The patient, a well-nourished and intelligent man of good habits, had never been sick from childhood, and reported a remarkably good family history. For some time previous he had noticed a gradual deterioration of health, as manifested by persistent insomnia, coated tongue, loss of appetite, mental and physical lassitude and an increasing tendency to constipation. A careful physical examination gave no clue to the cause of the above symptoms, save visual evidences of a rather pronounced anemia. Examination of the blood gave 2,500,000 red corpuscles to the c. m., while the hemoglobin remained about normal, 85 per cent. Some slight accentuation of the second sound of the heart was discernible. The urine was concentrated, reddish in color, specific gravity 1018, with absence of both albumin and sugar.

Three days later (March 6) I was hastily summoned to the bedside of my patient, who had suddenly been seized with a most excruciating attack of colic with attendant marked constipation. The pain was most severe in the neighborhood of the umbilicus, intermittent in character and decidedly relieved by forcible pressure during the attack, while marked hyperesthesia was manifested during the intervals, so that even superficial pressure was badly supported. The abdomen was decidedly retracted and the liver dullness apparently slightly diminished. The tongue was white, flabby and tremulous and there was now apparent, for the first time, a faint bluish line at the margin of the teeth. Temperature 97.3-5. Urine specific gravity 1014, absence of sugar and albumin, but subsequent examination exhibited slight traces of lead.

Evidently the case was one of lead poisoning, and appropriate treatment was therefore instituted, but the interesting question remained as to the manner of entrance of the poison into the system. Although distantly allied to that of house painter, the occupation hardly gave answer to this query, and it was only after careful investigation that the following interesting fact was elicited. The patient had recently married, and the newly made wife had, with commendable neatness, objected to an old-established habit of the husband, which consisted in wiping his brushes on his clean linen. Accordingly our patient now refrained from that, but after more or less completely cleansing his brushes, would now pass them between his lips. This condition of affairs had only been in progress for about six weeks before the commencement of the above detailed decided symptoms, beside which, as was pertinently remarked, his mode of life, residence, etc., had otherwise remained the same.

Under treatment, the attack gradually diminished in intensity so that on March 9 the colicky pains had almost disappeared. The blue line on the gums had, however, become more intensified and a well-marked patch similar in character was now observed on the mucous membrane of both cheeks. These patches

became white in color when the mouth was washed out with oxygenated water, as pointed out by Gubler, nor were there other evidences of a speedy convalescence. On the contrary, headache, dimness of vision, general muscular as well as arthritic pains now became prominent, as well as slight palsy of the right arm. An examination of the eyes was made at this time, but revealed nothing typical. The above symptoms continued, notwithstanding the treatment, until March 14, when while on the street our patient after experiencing a decided feeling of malaise, suddenly fell to the ground, seized with an attack of convulsions. He was at once removed to a neighboring saloon and two hours later to the Pennsylvania Hospital. At the time of his admission a violent delirium manifested itself, and continued without interruption throughout the entire night.

On the following morning his condition being unchanged and no history being obtainable, the hospital authorities decided to transfer him to the insane department of the Philadelphia Hospital when his wife discovered his whereabouts and took him home.

At this time, March 15, the delirium was extremely violent and continuous, and it was found necessary to strap the patient to the bed to prevent his bodily injury. Temperature 101 $\frac{3}{4}$ . A small quantity of urine drawn from the bladder gave evidence of the continued absence of both albumin and sugar. Contrary to the established rule in these cases there was no period of somnolence, and notwithstanding the administration of large doses of soporifics, both by the stomach and by hypodermic injection, it was found to be utterly impossible to produce sleep.

On the morning of March 16, the condition remained unchanged, with the natural exception of evidences of failing strength. At about 11 A.M. a severe convulsion occurred which was repeated at 1 P.M., at the hour of my arrival. This was general in character and after having lasted some fifteen minutes I had recourse to the anesthetic effects of ether. After a rather large quantity had been administered I had the profound satisfaction of noting the cessation of the convulsive attacks and the beginning of a long and profound sleep. This continued for a period of seven hours, at the end of which time there was a sudden awakening with complete restoration of consciousness and the entering into a subsequent speedy convalescence.

It is interesting to note that an examination of the urine immediately following the convulsive attack showed for the first time the presence of albumin in a fairly abundant quantity, without, however, any casts. A slight trace of sugar was also discernible on this occasion.

The question as to the exact cause of these cerebral symptoms does not seem to be much further advanced than in the time of Tanquerel. Recent post-mortems of cases of this kind made by Renant shows the brain substance to be yellowish, harder and more friable than normal, and chemic analysis shows the distinct presence of lead in the cerebral tissue. But these same conditions have also been noticed in other cases of lead poisoning which had not presented cerebral symptoms.

Therefore, besides the direct action of the lead on the brain cells we should, I think, admit the action of the poison on the cerebral vessels themselves, which may produce subsequent hemorrhage or softening to the parts supplied.

The question of uremic poisoning, as explanatory of this condition, should more properly be regarded as exceptional, instead of the general rule. Not only is albumin more often absent than present, but when found in only a moderate amount and not associated with other evidences of renal disease may very well be due to the rapid disintegration of the blood corpuscles, which we know does now occur and which usually marks the exacerbation of the general condition. Besides which we have the temporary albuminuria immediately following the convulsive attack.

As pointed out by Hayem, the blood changes are those showing a marked loss of red corpuscles and a normal percentage of hemoglobin, the white corpuscles being unaltered. Chemic analysis of this fluid will show the presence of lead.

Quite recently Debove, Achard, Charcot and others have given us strong evidences tending to prove that many of the so-called cases of saturnine apoplexy are distinctly hysterical in nature and readily respond to the special treatment. They point out that hemianesthesia may appear early in the case, or, on the other hand, after apoplectic or convulsive seizures. The above condition may exist alone or accompany a motor hemiplegia with abolishment of sensation to contact, pain and temperature, with feeble or suppressed vision, hearing, taste and smell. Some peripheral reflexes may persist, but the pharyngeal reflex is generally abolished.

In a rather large experience in case of lead poisoning I have recently had reason to confirm the views of the above writers, namely, that in a fair proportion of cases many of the symptoms formerly attributed to the direct action of the lead, such as anesthesia, a hyperesthesia of local parts, much of the headache, etc., may be more successfully treated by the bromids than by the iodids. According to the views of the above authors, the existence of hemianesthesia is proof of the hysterical nature of the affection.

This may also explain the relative frequency of cases of lead encephalopathy, found in recent medical literature, with a proportionate lessening of the mortality records. Tanquerel, in his large experience, met with but seventy cases which presented mortality of about 80 per cent., and at the present day, men of wide experience and careful observation mention its rarity as well as continued high death rate.

A short time since I treated two cases of so-called lead asthma, on the above theory, with such prompt and satisfactory results that I think the fact merits special attention. In both of these cases I noted that the expiratory dyspnea was not so proportionately marked as in cases of true asthma. As the symptoms are otherwise identical, with the exception that they disappear when the special poison is removed from the system, the above fact if further corroborated may prove to be of diagnostic importance.

*Trophic Changes.*—Gubler points out that the dorsal tumor of the wrist which has long been considered pathognomonic of lead poisoning, is a swelling of the sheaths of the extensors as a result of the paralysis of the posterior muscles of the forearm. This is an indolent tumor, generally about the size of a pigeon's egg, situated on the dorsal aspect of the wrist, hard and resisting to the touch and movable with the extensor tendons.

Regarding the treatment of the encephalopathy but

little can be said other than that it should be symptomatic. Undoubtedly the main indication is to produce sleep, as experience teaches us that the longer the patient remains in this condition the less apt is the case to terminate favorably. Permanent insanity has resulted.

The anesthetic effect of the ether followed by a long sleep, as in the case reported in this paper, would, I think, prompt me to make earlier use of this agent if other remedies fail.

Just one word more as regards the treatment of the lead colic and constipation. Following the teaching of recent French authorities, I have made use of large doses of olive oil, in half a dozen or more cases, with apparently more satisfactory results than by the use of magnesia and other drugs. In three of the above cases, the use of the oil relieved the pain before the bowels were opened, and I think this treatment merits further attention. Cocain or other similar remedies may be necessary, however, to cause the stomach to retain this medicament.

## A STATISTICAL STUDY OF THE COMPLICATIONS OF MALARIA.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY J. M. ANDERS, M.D., Ph.D.

PROFESSOR OF MEDICINE AND CLINICAL MEDICINE AT THE MEDICO-CHIRURGICAL COLLEGE; PHYSICIAN TO THE PHILADELPHIA AND MEDICO-CHIRURGICAL HOSPITALS, PHILADELPHIA.

In this paper I have endeavored to present carefully collected statistics, which establish certain facts pertaining to a number of complications of malaria. That not a few of the conclusions arrived at are at variance with the pre-conceived notions of many of his readers, the writer fully realizes, but he hopes that he has not fallen into the error of basing those conclusions upon too slender evidence. Everything of an argumentative nature has been excluded, in order to bring the paper within the time limit of the Section on Practice. Accordingly, the article is, for the most part, a mere statement of facts and figures which must speak for themselves, and from which a few not unimportant deductions it is hoped may be drawn. To the literature of the subject brief reference only has been made.

The total number of cases which were analyzed and form the basis of the present paper were 2,122. Of these, 1,132 cases were furnished by the records of the Pennsylvania Hospital, extending over a period of twenty-one years (1873 to 1894 inclusive); 611 cases were furnished by the records of the Philadelphia Hospital, during eight years (1886 to August, 1894, inclusive), and 379 cases by the Episcopal Hospital, the latter occurring during the decade recently ended (1885 to 1894 inclusive). In this connection I desire to express my deep obligation to Dr. Morris Booth Miller, without whose kind assistance the data obtained at the Pennsylvania Hospital could not have been procured.

The notes of the cases gleaned from the records of the Pennsylvania Hospital, those gleaned from the records of the Episcopal Hospital and also those from the Philadelphia Hospital from 1889 to August, 1894, inclusive, were found to be complete enough to serve as a safe foundation for inferences, not without considerable practical value. They embrace 1,780 cases of malaria. These 1,780 cases were carefully analyzed with reference to their complications which were

noted in 189 instances or 10.7 per cent. The cases were found to be classified, as follows:

Intermittent fever (including quotidians, tertians, quartans, etc)	1,434
Remittent fever	75
Malaria cachexia	27
Chronic malaria and irregular types	22
Unclassified	222

Total . . . . . 1,780

Again, all instances in which an element of doubt was presented by the diagnosis were eliminated. In the majority of the cases the blood appearances were given.

But though the proportion of cases of malaria in which complications arise, is as great as in some of the other acute infective diseases, yet they are somewhat peculiar in character and, on the whole, not grave in nature, as may be observed by an inspection of the subjoined list, in which they are placed in the order of frequency of occurrence:

Heart disease:—Valvular heart disease	14
Valvular heart disease, comp. with albuminuria	4
Mitral regurgitation and congest. lungs	1
Mitral regurgitation—died	1
Dilatation of heart	1

Total . . . . . 21

Enteritis:—Simple	16
Gastro-enteritis	3
Chronic	1
With albumin and granular casts	1

Total . . . . . 21

Neuralgia:—Supra-orbital	11
Intercostal	2
Anterior crural nerve	1
With ptosis and left side corneal ulcer	1
Double sciatica	1
Gastralgia	1
Facial	1

Total . . . . . 18

Albuminuria:—(Marked)	14
-----------------------	----

Pleurisy:—Simple (plastic)	10
With effusion	1
With nephritis	1
With heart failure	1

Total . . . . . 13

Rheumatism:—Simple (articular)	10
Syphilitic (two with systolic murmur)	3

Total . . . . . 13

Phthisis:—Chronic	7
Chronic incipient	4
With albuminuria	1

Total . . . . . 12

Typhoid fever:—(Typho-malaria)	8
--------------------------------	---

Edema:—With anemia	2
Of feet and legs	2
Of legs	1
Of legs with abscess	1
Of feet with enlargement lymphatic glands	1

Total . . . . . 7

Pneumonia, lobar:—Simple	3
Double croupous—1 with fatty heart, died	2

Total . . . . . 5

Pneumonia, catarrhal:—Simple	1
------------------------------	---

Juandice:—Catarrhal	4
Catarrhal intense with melena	1

Total . . . . . 5

Nephritis:—Simple	2
Chronic parenchymatous	1
Acute and pleurisy with effusion	1
Acute Bright's	1

Total . . . . . 5

Anemia	4
Dysentery	4
Syphilis (1 tertiary)	3
Goitre (1 exophthalmic and enlarged inguinal glands)	3
Erysipelas	3
Gonorrhea	3
Ascites (1 with edema of feet)	2
Hepatitis (1 chronic)	2
Paraplegia	2
Constipation	2
Hemorrhoids and lithemia	1
Biluria	1
Dyspepsia (atonic)	1
Hematemesis	1
Mal. neuritis	1
Hepatic catarrh	1
Hystero-epilepsy	1
Epileptic convulsions	1
Saturnismus	1
Enlargement of thyroid glands	1
Enlarged lymphatic glands	1
Paralysis of bladder	1
Vertigo	1
Cerebral congestion with effusion into ventricles	1
Cervical adenitis	1
Follicular sore throat	1
Zoster femoralis	1
Abscess of groin	1
Phlegmasia albadolene	1
Epistaxis	1
Pericarditis	1
Hyperpyrexia	1
Toxemia	1
Cystitis	1
Typhlitis	1
Brachycardia (pulse 44 to 56)	1
Stricture	1
Alcoholism	1
Ague-cake spleen	1

Some of the conditions, which have been recorded as complications, should more properly be regarded as being symptomatic indications of the malarial process. These will, therefore, not receive further consideration at present writing. Again, some of the chronic affections which have been noted as complications such as chronic valvular diseases of the heart, pulmonary tuberculosis and nephritis were, in all probability, in many instances preëxisting affections, which most probably predisposed on account of their debilitating influence to malarial infection. *Per contra*, I entirely agree with the view expressed by the late Austin Flint, that there is reason to believe that malaria promotes the development of phthisis pulmonalis in those predisposed to it.

Among the most frequent complications stands neuralgia, of which there were eighteen instances (supra)<sup>1</sup> out of the sum total of cases, and eleven of these it may be seen involved the supra-orbital branch of the fifth nerve. In these investigations both pleurisy and rheumatism were found to be relatively frequent, complicating conditions, though each occurred in less than 1 per cent. of the cases. The literature of malaria contains but few allusions to the circumstance that pleurisy may arise in its course. Whittaker<sup>2</sup> states that malaria may simulate pleurisy and other diseases. I can not stop to consider the question whether or not the implication of the pleura, in cases of malaria, is dependent upon the primary

<sup>1</sup> Text-book of the Practice of Medicine, 957.

<sup>2</sup> Theory and Practice of Medicine, 957.

infection. I think it quite probable, however, that it is more frequently due to secondary infection, hence, it is to be looked upon as a genuine complication. I find no mention in medical literature of the fact that rheumatism is, comparatively speaking, a not uncommon concomitant of malarial toxemia, as is indicated by the present researches.

Upon the question, "Has pneumonia any special connection with malaria?" the opinion of the profession is divided. Physicians residing in the highly malarious districts of warm latitudes have been, since old times, and are still, describing a malarial form of pneumonia. To illustrate: J. P. Frances,<sup>3</sup> (Carenro, La.), in an article on "Malarial Pneumonia" states: "Malarial pneumonia has been very rife during this present spring, 1889. The severe type manifests itself first by several paroxysms of intermittent or remittent malarial fever. Pneumonia will then set in with slight rigors followed by headache, flushed face, soreness in the chest." . . . "Fever averages about 103½ to 104 degrees F. Examination of the chest reveals an alteration in the affected side; a bruit rougher than on the opposite side. A whole lobe is usually involved, beginning indifferently and in about equal proportion, either at the base or the apex.

"Frequently the crepitant râle is not dry at the end of the act of inspiration, and is often substituted by bronchitic respiration." . . .

"Percussion gives negative results or a slight alteration. Sputa vary from frothy mucus to pathognomonic ones of classical pneumonia.

"The paroxysm generally continues for thirty-six or more hours; the fever then abates or intermits and with it the chest troubles. Should the case be intermittent, a few scattered râles will be found by auscultation; in the remittent type the bronchitic respiration is ameliorated, and we have the *redux* râle." . . .

"After a couple of hours of respite, the paroxysm sets in anew, with chest symptoms much more severe, and remits once or twice again, after some thirty hours each, making the case last from the onset to the end of the attack, five or six days."

Frances further points out the fact that when cases end by death, little or no remission occurs after the second paroxysm, the condition merging into a typhoid state terminating in death. He also describes double malarial pneumonias, after which he continues: "I have seen a lady, multipara, with a double malarial cataleptic pneumonia. The chest and nervous symptoms increased and decreased with the febrile movement; she died on the seventh day. This case was of the remittent type, temperature 100 to 105 1-9 degrees F. Chances in double pneumonia are half and half; and with children about three to one."

Martin<sup>4</sup> reports a case of malaria complicated with pneumonia, which occurred in the Montreal General Hospital. In this case, which came to autopsy, the right lung was found to be in a state of gray hepatization, the organs all bile-stained, the spleen not enlarged. The patient was a male Indian (traveling with a circus), age 51, whose illness began with a severe rigor, lasting one hour, twelve days prior to admission (namely Oct. 23, 1892) attended with fever and great sweating. Subsequently, had daily recurring chills, followed by hot and sweating stages, till date

of admission. Temperature on entering hospital (November 4) 105½, pulse 122, respiration 36. . . . No chills developed after entering hospital, but there was great prostration. The characteristic malarial symptoms now seemed to be conspicuous mainly by their absence. There was no herpes; no enlargement of the spleen or liver could be made out. The respiratory system presented the most prominent local symptoms. The sputum consisted of muco-pus.

*Physical Signs.*—For some time these were, for the most part, anything but typical. Thus the respirations were 24, costo-abdominal expansion of the chest good; tactile fremitus normal, percussion revealed no dullness. Auscultation: the breath sounds were harsh in both infra-clavicular regions, where, also a few moist râles were heard. Elsewhere no adventitious sounds; vocal resonance normal. Blood examination showed presence of plasmodium malariae in various forms, especially the amoeboid and free pigmented varieties.

On November 11, the temperature was 101½, respiration 20, pulse 88. Lungs examined but found negative. Two days later dullness appeared at base of right lung and crepitant râles with diminished breath sounds on auscultation. Great weakness and severe dyspnea with blood-tinged expectoration soon followed. The area of dullness increased; jaundice appeared, which grew quite intense. Examination for bacilli negative. The right lung now showed signs of consolidation from base up to the spine of the scapula. Death occurred November 18. (See result of autopsy, supra.)

One of the instances of pneumonia embraced in the above table of complications proved fatal. It occurred in the service of Dr. James H. Hutchinson at the Pennsylvania Hospital. The patient, a male, age 57, was admitted to the medical wards April 25, 1880. Had never been sick except during previous fall when he had ague lasting several days. Three days prior to admission he had diarrhea, fever and sweating, the following day a similar paroxysm. On the day of admission he had high fever about 6 A.M., followed by profuse sweating after he was admitted. At 4:26, fever this A.M., and sweating but comfortable; 4:27, sub-crepitant râles heard; 4:28, slightly more cough with frothy expectoration; 4:29, dull under the clavicle and posteriorly over lower part of right lung. The respiration bronchial. Vocal fremitus and resonance increased; 4:30, died at 8:30 o'clock A.M.

Post-mortem: rigor mortis firm. Old adhesion at right apex and diaphragm. Recent lymph at right base. Left lung fills pleural sac. Recent adhesions. Few bands of recent lymph in left side of pericardium. Heart contains 2 ounces cloudy serum. Both sides of heart relaxed. Right auricle filled with black clot. Firm chicken-fat clot in right ventricle. Left auricle contains chicken-fat clot extending into vessels. Mitral valve atheromatous; aortic valves thickened and fenestrated. Left ventricle wall thickened but softened. Weight 18 ounces. Left pleura contains some blood serum. Right lung, anteriorly, is crepitant and in places emphysematous. Border of lower lobe crepitates imperfectly. Section shows lower lobe to be in a stage of red hepatization; middle in later stage and upper presents a mixed appearance. Several old cheesy masses in apex, but one in middle lobe. Posterior part of left lung firmer than anterior. The latter is gray, firm and less elastic. Two lungs weigh six pounds. Spleen slightly larger. Fibrous tissue increased, dark-colored. Kidneys, left kid-

<sup>3</sup> The Times and Register, vol. XX, 1889, p. 345.

<sup>4</sup> Service of Dr. Stewart, Mont. Gen. Hospital, (Montreal Medical Journal, vol. XXI, p. 900).

ney large and irregular. Large cyst near pelvis, size of plum. Weight eight ounces. Deeply congested. Capsule slightly adherent; not thickened; leaves smooth surface. Right kidney small. Less congested, and on posterior surface there is a small doughy cyst and a small cyst on surface of larger one. Liver, gall-bladder filled with dark mucus and bile, borders rounded, dark-colored and firm. Surface somewhat homogenous. Weight, five pounds, four ounces.

In a fatal case of pernicious malaria under the care of Musser at the Philadelphia Hospital, the post-mortem records showed that there had been marked edema of the lungs, which had been supposed to have been the cause of death. No mention was made of the presence of the characteristic lesions of pneumonia.

D. E. English<sup>5</sup> in a paper on "Pulmonary Inflammation as a Complication of Malaria," contends: "Sometimes at the end of the first or the beginning of the second week of a case of remittent fever that has not responded well to the usual treatment, we find our patient with a little higher temperature, a little sharper pulse, a little quickening of the respiration, a very slight occasional cough, and just a suggestion of difficulty in breathing. A careful examination of the chest reveals one or more spots of beginning inflammation in the lungs. This patient does not have a true croupous pneumonia, but he does have an inflammation of lung tissue, occurring as a complication of remittent fever. In this connection, it should be pointed out, that all the instances of pneumonia that occurred in the present series of cases of malaria, arose in the course of intermittens.

The physical signs are similar to those of true croupous pneumonia, except that the dullness on percussion comes on more abruptly and is not so absolute as in true pneumonia, and probably because the air-cells are not so completely filled and the exudate is liquid. The subcrepitant r  le can be heard and sometimes the sounds of a coarser bronchitis. As a rule, the sounds of fine bronchitis are heard only in the immediate neighborhood of the spot.

"The general symptoms of remittent fever, the temperature running higher than it otherwise would, and the remission not being so distinct as usual. The pulmonary inflammation subsides when the systematic disease has been brought under control."

He further states that "this complication may be mistaken for true croupous pneumonia, lobular pneumonia, capillary bronchitis, simple congestion of the lung and pulmonary edema."

Says Osler:<sup>6</sup> "A malarial pneumonia is described and is thought to be very prevalent in some parts of this country. Although I have seen during the past seven years several hundred cases of malaria, and am familiar with the bronchial troubles so commonly associated with it, I have yet to see an instance of pneumonia, which seemed in any way connected with paludism." Again,<sup>7</sup> he relates his personal experience with the combined occurrence of these two affections, as follows: "On two occasions in the Philadelphia Hospital I had an opportunity of seeing the development of pneumonia in convalescents from malaria, one of the quotidian, the other of the quartan type. They developed in a ward with several other cases of pneumonia, but the disease ran a

perfectly normal course. In about four hundred cases of malaria, which have been under observation at the Johns Hopkins Hospital and Dispensary, bronchitis has been frequent as an early symptom, but we have seen no indication of any special form of inflammation of the lungs."

According to the present collective investigation, out of the aggregate number of cases of malaria analyzed—1,780—only 5 cases of lobar pneumonia and 1 of catarrhal pneumonia occurred. Thus, lobar pneumonia can not be regarded as being frequently in association with malaria, and yet that it is so, rarely, can not be denied, in view of the clinical and post-mortem evidence at our command. So far as can be ascertained from the notes of the cases, the symptoms presented were the same as those met with when pneumonia complicates other acute infective diseases, though the physical signs were, perhaps, less pronounced for two or three days after the onset. Further, the results obtained by these observations are entirely confirmatory of the view expressed by Osler (supra), when he affirms that pneumonia has no special relation to malaria. Now, while this is true as regards the occurrence of pneumonia secondary to malaria in Philadelphia and other temperate latitudes, it may be equally true that the severer forms of the disease, which occur in warm climates, truly invite invasion of the lung by the pneumococcus of Fraenkel.

A glance at the table of complications will show that, in six of these instances, typhoid fever was noted. That there is a class of cases in which both malaria and typhoid fever are met with in the same individual, simultaneously, can not be doubted. In view of the results, however, obtained by these researches, that relationship can not be close. Neither is the compound affection due to a third extraneous "compound agent," as was formerly believed, but to the effects of the two pathogenic organisms in one body at the same time. The hybrid occurs most frequently in the malarious regions of our Southern States. I hold that a careful blood examination in suspected typho-malarial fever would show many instances to be pure typhoid fever. The presence of chills and sweats and an intermittent temperature curve are sometimes observed in typhoid. Furthermore, when the temperature curve is of the intermittent type, from the beginning, the course of the affection is usually favorable. This fact tends to make clear the meaning of Woodward's statistics, which show "that the mortality of uncomplicated typhoid was far greater among the white and colored troops alike, during our late Civil War, than was the mortality of typho-malarial fever."

1603 Walnut Street.

#### DISCUSSION.

DR. ROCHESTER—This subject of the connection of malaria with other forms of disease is one of exceeding interest to us all. There is one thing I should like to ask the doctor. He speaks of the complication of malaria with pleurisy. I should like to know whether he has notes in the cases in which that occurred and whether the majority occurred on the left side or not. Also, in pneumonia, he mentioned that one case was on the right side. I think there is some possible explanation offered for its occurrence on the left side in connection with the spleen. I am glad he spoke of the fact that true lobar pneumonia was so exceedingly rare in the malarial fevers, but that we did have very commonly a complication of the respiratory tract, principally confined to the bronchial tubes, with occasional true bron-

<sup>5</sup> Abstract of a paper read before the Orange Mountain Medical Society, August 14, 1891, Medical Record, March 11, 1893, p. 297.

<sup>6</sup> Practice of Medicine, p. 551.

<sup>7</sup> Loc cit. p. 146.

chial pneumonia or lobular pneumonia associated with it. It seems to me that careful discriminations should be made between what we call true lobar pneumonia and bronchopneumonia in all cases, a thing which is frequently overlooked when people speak of pneumonia. The complication of typhoid fever with malarial fever is of interest, and also the fact the Doctor has brought out, and which should be particularly emphasized, that we do have cases of typhoid fever in which the temperature remits, in which there is no malarial complication whatever. We should not describe a case of typhoid fever as malarial unless we actually find in the blood the plasmodium of malaria.

DR. HOLLISTER—In the early years of my medical practice I came directly in contact with more cases of malarial complications than all others combined, and among a class of people who had not been theretofore exposed to malarial influence and therefore in whom we could trace easily the depressing influences and constitutional effects of the presence of malaria. Universally it was found—although we knew nothing of the plasmodium of malaria—that one of the manifestations most marked in connection with these diseases was the destruction of the red blood corpuscles. The first summer I had no trouble with malaria, and my patients responded readily to the usual remedies. When in November and December I came to see these persons subjected to the low temperatures and to the other influences incident to the winter, I began to find a series of manifestations, which took the form very largely of an epidemic of congestion. This even took the form of cerebro-spinal meningitis, with fatal results. The second year, however, the manifestations were not upon the nervous centers, but more markedly they were pulmonary complications. Why in those two years the complications were so different in the same locality I can not say. The second year in almost every instance there were catarrhal manifestations, and then very rapidly a series of others in which there were infiltrations into the lungs. Large numbers of cases were fatal. Some of these cases were accompanied by pleuritis complication, but perhaps not more than 10 per cent. There were cases in which there was dullness, first posterior, and then extending gradually from the base and involving more and more of the respiratory tract areas, with fatal results in the manner I have indicated, and it had seemed to me that the inflammatory phenomena of that form of inflammation of the lungs were due to the great destruction of blood corpuscles and the enfeeblement of the body. If there are present any cocci or tubercle bacilli, they here met with the conditions most favorable for their development. In proportion as the blood was improved, resistance was more manifest, and favorable results could be obtained in the treatment. I have the impression that where the plasmodium is not present, you will not find any relation between malaria and tuberculosis. I am convinced that where the plasmodium of malaria and the tubercle bacillus are both present, either one will prepare the way for more serious manifestations on the part of the other.

DR. ANDREAS—As to Dr. Rochester's question with reference to the relative frequency of the occurrence of pleurisy on the two sides, I can not reply in positive terms, as the cases were not studied with regard to this point, although I think this might have been done with great advantage. I may say that my recollection is very clear as to the variety—clinical and pathological—or that most of the instances were cases of plastic pleurisy, there having been only a few in which sero-fibrinous exudations occurred to any extent. Dr. Hollister made the point that season influences the character of the infection. I do not doubt that this is true, and more especially do I believe that the winter season predisposes a patient suffering from malaria to pulmonary complications in particular. If my recollection serves me, this was true of the cases which occurred in Philadelphia, so far as this complication was concerned. We must remember the fact, however, that both forms of pneumonia are on the whole much more frequent during the winter than the warm season of the year. He also made the statement based upon personal experience that the epidemic varied as regards the character of the complications. Now, in Philadelphia this disease does not occur in epidemic form, at least not to any extent among the cases that are admitted into the hospital. The statement made by Dr. Hollister, however, simply confirms a well-known fact with reference to all other acute infectious diseases, namely, that not only the type of the infection, but also the character of the complications, varies to a very great extent in different epidemics. I think I have shown clearly enough that typhoid fever and pneumonia do not bear any

special relation to malaria. The fact was also forcibly brought out that pleurisy and rheumatism are, comparatively speaking, frequent complications of malarial infection. This is of interest from the fact that we do not find any reference to the connection either in our text-books or in the literature.

## CONSTIPATION AND FAULTY ELIMINATION AS A FACTOR IN DISEASE.

Read in the Section on Practice of Medicine at the Forty-sixth Annual Meeting of the American Medical Association at Baltimore, Md., May 7-10, 1895.

BY FREDERIC S. THOMAS, M.D.

COUNCIL BLUFFS, IOWA.

The retention of fecal accumulations in the alimentary tract, and their discharge but once a day is an acquired habit. Primitive man, like other unrestrained animals, defecated more often.

The result of retaining within the body matter so poisonous, can not be other than prejudicial to health.

Man, the most perfect of animals, intellectually far in advance of all others, is nevertheless ignorant as to what food he should select. The result of this is imperfect digestion, constipation and faulty elimination. Each largely depends upon the other. Viewed from the standpoint of digestion, (intestinal,) let us briefly consider this important process.

We are told that "harmony of the secretions means normal cell selection, and normal cell selection means health." Any deviation from these relations means "cell disturbance, or disease."

The digestive changes in the small intestines may be summed up as follows: proteids are converted into peptones by pepsin and trypsin, because albumins are not readily absorbed by the circulatory and lymphatic systems.

We have also been taught that peptones can not exist in the blood as peptones, without poisonous effect, but must be converted back into their native albumins (proteids). The pepsin of the stomach begins the process of digestion. Trypsin of the pancreas completes it, carrying it a step further, producing leucin and tyrosin. Then comes absorption, etc. Thus, cane sugar is converted into grape sugar, by invertin from the crypts of Leiberkühn. Steapsin of the pancreas is the active agent in the emulsification of fats. The liver cells are called upon for bile to assist in their absorption. If we study intestinal digestion, we readily see the important function of the liver in the process, as well as the importance of a portal circulation which is unimpeded.

We are taught that "any interference with the pancreatic cells would interfere with the proper solution of proteids into peptones, and the formation of leucin and tyrosin. A modified product of digestion would be taken to the liver, and the liver cells could not convert them properly into urea." Interference with the action of the liver cells would produce auto-infection, and its symptom would be non-elimination.

What would be the effect upon the normal cell activity, in the process of intestinal digestion, of blocking up the lower end of the tube (the bowels)? Would we not have modified cell activity, and would not materials that were poisonous be crowded into the circulation; and if in sufficient quantities, would not this produce death?

When ptomaines, leucomaines, ferments and chemical derivatives of digestion are considered, we see how

important cell selection becomes in the normal functional activities.

Since our profession have been so assiduously studying the microorganisms which are about us, upon the supposition that our diseases come from without, we have forgotten that the microorganisms which dwell within, whose names are legion, are being neglected.

How important it is, therefore, to prevent accumulations of effete materials within the intestinal tract. Branton attributes the "depression, lassitude and dullness after a full meal, in the full-fed, inactive man, to peptones in the blood." Ought we not likewise to attribute many forms of disease to constipation and the faulty elimination of poisonous material from the alimentary canal?

Our food consists of proteids, carbohydrates, hydrocarbons, salts, and water. In their preparation in the alimentary tract before absorption, certain chemical changes take place. This requires normal functionation, or especial selective acts. If all alimentary substances were taken up by the blood, death would undoubtedly ensue. Hence the importance of normal cell selection during secretion, absorption or elimination. Poisonous substances are formed, which, if retained in the tissues, would become a source of infection. The cells would poison themselves by the products of their own metabolism.

Should the pancreas fail, in its cell selection, to produce trypsin from the blood by reason of any interference, a modified product of digestion would be taken to the liver. Urea would appear in the circulation, and symptoms would arise, which, if not eliminated, would be followed by dangerous results.

Bouchard informs us that sufficient poisonous matters are formed in the intestines every day to produce death should they be absorbed into the circulation.

Many of the so-called "diseases of the nervous system," arise solely from auto-infection, and require nothing but corrected digestion and proper elimination. Thus many febrile diseases during the months of autumn become grave only because of retained fecal infection.

We can truthfully say, therefore, that constipation and faulty elimination are important factors in disease.

## CIRRHOSIS OF THE LIVER.

### CLINICAL AND PATHOLOGICAL DIFFERENTIAL DIAGNOSIS, WITH CASE.

Read before the Chicago Pathological Society, Feb. 11, 1895.

BY ARTHUR R. EDWARDS, A.M., M.D.

PATHOLOGIST AND PHYSICIAN TO COOK COUNTY HOSPITAL; INSTRUCTOR IN MEDICINE AND PHYSICAL DIAGNOSIS NORTHWESTERN UNIVERSITY MEDICAL SCHOOL.

CHICAGO, ILL.

Patient was a Norwegian, married, 48 years old and a laborer. Under observation thirty-four days. Previous diseases: measles, colds, pneumonia four years ago. Family history negative. Personal history: in Chicago twenty-three years; married twenty-two years; three healthy children; smokes and chews; drinks moderately; venereal history denied. Present disease: ill for three weeks beginning with pain in epigastrium and hypochondria, which is at times absent, now dull, now shooting into both shoulders; dizziness on walking; weakness with pain in lumbar regions; no pain on inspiration; has not vomited; no hematemesis; eats less frequently

because of pain produced in epigastrium; during past month has emaciated rapidly; bowels regular; appetite good; never jaundiced; occasional eructations of gas; coughs a little in the morning.

Physical examination: considerable emaciation; muscles flabby; mind clear; eyes negative; tongue clean; mouth negative; lungs negative. Heart: systolic blowing, apical murmur, diagnosed accidental. No marked atheroma. Pulse somewhat quick but rhythmic; frequency varies from 80 to 104. The morning temperature averaged 99 degrees, the evening 101 degrees, preserving this type with fair constancy. Four evening elevations of 101.8, 102, 102.2, and 102.2 were observed. Urine negative; not bile stained. Feces normally pigmented. Stools irregular in frequency, constipation alternating with slight diarrhea. Nervous system negative.

The liver conformed to the normal contour above, moving freely on respiration; it extended three inches below the usual inferior limit, the enlargement being symmetrical. The edge, not readily palpable because of tenderness, seemed even. The hepatic tenderness and epigastric pain were constant. There was no conspicuous tympany. The splenic dullness was always uncertain, as the organ was never palpated and constipation was frequent. Lastly, the skin of the patient was dry and muddy, and his appearance cachectic. No icterus was observed. Neither hydrochloric nor lactic acid was present in the gastric juice.

The blood count gave 4,104,000 red blood corpuscles, and the red corpuscles sustained to the whites a ratio of 1 to 174. Later counts showed gradual reduction in the number of red corpuscles to 3,800,000, while the leucocytes were to the erythrocytes as 1 to 125.

The patient for several days prior to death was delirious and vomited. The treatment was directed chiefly to his cough and nausea. Antisyphilitic treatment was given. The diagnosis would have been Laennec's cirrhosis in the first stage, had there been collateral circulation, a caput medusæ, ascites, splenic tumor or any gastro-intestinal hemorrhage. Hypertrophic cirrhosis was considered but rejected because no spleen could be found and icterus was absent, although that form of biliary cirrhosis, known among French authors as hypertrophic cirrhosis without icterus, was thought of and discussed in the clinical conferences. The rapid emaciation suggested neoplasm and the leucocytosis looked toward some suppurating focus, although no confirming facts were established.

The autopsy showed little outside of the liver. The aorta and the peripheral vessels were atheromatous. Heart negative; lungs, marginal emphysema, few adhesions and ancient healed tubercular foci. The liver weighed 2,730 gm.; there were a few perihepatic adhesions; the organ measured 29 x 19 x 20 x 8.5 x 5.5 cm. The capsule was here and there thickened, but the edges and surface were perfectly smooth. On section the lobules appeared quite large, some measuring 1 cm. across. The color was mottled yellow and red. The organ was firm and had a waxy appearance simulating amyloid. The spleen weighed 420 gm. and measured 15 x 12 x 6 cm. The kidneys weighed 530 gm., and measured 14 x 8 x 4 cm. The capsule peeled very readily, and the markings were fairly distinct. The cut surface was dark and very vascular, the kidney of passive congestion. On microscopic exam-

ination is found an increase in the inter- and intra-lobular connective tissue of the liver. Round cells are found in every part of the lobule and in some places the lobule is wholly replaced by them. The liver cells are now larger than normal, now atrophic, never fatty nor pigmented. The bile ducts are increased. Occasionally a very large lobule is found.

The most interesting pathologic feature in this case is the status of the cirrhosis, whether it is the first stage of a Laennec's cirrhosis, an hypertrophic alcoholic cirrhosis, a biliary cirrhosis or a mixed cirrhosis. It is certainly not a typical Laennec's cirrhosis.

A consideration of the possibility that the vulgar hepatic cirrhosis may be preceded by hypertrophy, is pre-requisite. Todd<sup>1</sup> claims that there is never preliminary enlargement in Laennec's cirrhosis and he was unable to find in literature a reliable instance of a hypertrophic passing into an atrophic cirrhosis. Stricker (Traube's clinic) observed livers shrink to half their former length in one month. Therefore subacute and acute hepatitis must be excluded. Rosenstein<sup>2</sup> and Labadie Lagrave<sup>3</sup> agree with Todd. Bright,<sup>4</sup> Budd,<sup>5</sup> Saunders and Frerichs<sup>6</sup> have said that contraction is occasionally antedated by a stage of enlargement. Murchison's<sup>7</sup> experience taught that in a considerable proportion of cases of cirrhosis, the liver is still very much enlarged, often from fat, after symptoms of portal obstruction have set in and that patients often die in this stage with jaundice, hemorrhage and symptoms of blood poisoning. Leudet,<sup>8</sup> from a pathologic standpoint comes to the conclusion that increase in liver volume is not always an index of a recent lesion, of an acute process or a curable one. Murchison says it is questionable whether such livers would shrink if the patient lived longer, yet he states that increase and decrease in liver volume are probably different stages of the same process. Ollivier<sup>9</sup> believed that cirrhotic atrophy and cirrhotic hypertrophy were different states. Gilbert and Hanot believe in the preliminary enlargement of cirrhosis atrophica. Semmola and Klebs have studied the disease in its incipency and found that the organ is firm, smooth and dark, with dilated portal radicles and periportal extravasation of round cells (Tissier). Keussner<sup>10</sup> Rokitsky, Stadelmann,<sup>11</sup> Litten,<sup>12</sup> Schapiro,<sup>13</sup> Mangelsdorf,<sup>14</sup> Niemeyer,<sup>15</sup> Stricker, Strümpell,<sup>16</sup> Hamilton,<sup>17</sup> Orth and Zeigler describe enlargement antecedent to atrophy. Bamberger<sup>18</sup> considers the decrease in size of an enlarged liver almost pathognomonic for atrophic cirrhosis. Rosenstein applies two tests, palpation of the liver's edge, continued clinical observation and necropsy—ascites, obstipation or tympany render percussion most uncertain. With these criteria Rosenstein has never seen atrophy following hypertrophy.

*Definition of term "hypertrophic."* — Hamilton<sup>17</sup> takes exception to the term "hypertrophy," arguing that an enlarged liver may be very atrophic. Liebermeister considers that the terms, "biliary" and "hypertrophic" are not identical, nor are venous and atrophic cirrhoses one. The portal vein form usually shrinks and the biliary form usually enlarges, but exceptions occur as, 1, portal vein forms remaining large till death; or 2, biliary types atrophying to a certain degree.

Most writers, e. g., Strümpell, regard "biliary" and "hypertrophic" as synonymous, and "venous" and

"atrophic" as the same. The hypertrophic alcoholic cirrhosis of Hanot and Gilbert<sup>18</sup> is characterized by edges less sharp than normal; red or brown color; surface furrowed by uneven areas, varying in size, the unevenness being less than in the atrophic form; by granulations on the surface; by enlarged spleen, ascites, collateral circulation, etc. They assert there are many transitional forms between it and the atrophic alcoholic cirrhosis, so that great importance does not attach to size alone. Recovery occurs in this more than in any other form.

Laennec seems to have known but one type of cirrhosis. Hanot, supported by Hayem, Cornil and Charcot, insisted even more than did Todd upon the divorce of hypertrophic and atrophic cirrhoses. This separation of the two forms is the constant theme of the French school, but they do not seem concerned as to whether an enlarged liver may become small.

Cornil<sup>19</sup> was the first to discover in the hypertrophic form, a very rich network of bile vessels and upon this Hanot based his clinical division of cirrhoses into, 1, the venous; and 2, the biliary. Litten and Mangelsdorf sought to show that biliary was but the first stage of the vulgar cirrhosis plus icterus. In Germany, the different cirrhoses are largely held to be mere variations of a single fundamental cirrhosis. Stadelmann<sup>11</sup> voices this opinion when he can not find a difference between the two forms for the following reasons: 1, there is a hypertrophic cirrhosis without icterus; 2, hypertrophic cirrhosis can later atrophy; 3, icterus can be very marked in Laennec's cirrhosis.

Rosenstein suggests three classes of cirrhosis: 1, the genuine contracted liver; the cirrhosis of Laennec, an analogue of the genuine contracted kidney.

2. The hypertrophic icteric cirrhosis, an analogue of the parenchymatous nephritis.

3. The hypertrophic mixed form, in which hypertrophy and atrophy combine, an analogue of the secondarily contracted kidney.

Ackermann distinguishes an atrophic cirrhosis (Laennec's) in which the cells die first and are replaced by connective tissue. According to him, Laennec's cirrhosis and one variety of large cirrhotic liver are the same, for in certain livers some parts are atrophic and others again are hypertrophic. Ackermann admits the identity of the French hypertrophic variety which has, he states, nothing in common with the atrophic cirrhosis except the connective tissue proliferation. It is apparently a primary connective tissue hypertrophy with consequent atrophy of liver cells, a hypertrophy occurring around the interacinous blood vessels, never leading to characteristic granulations, producing moderate or no stasis, i. e., scanty ascites and insignificant splenic tumor, and occurring also in horses, fowls and cattle, while the atrophic is seen in man only. The difference between this form and Charcot's description is obvious.

Charcot drew such sharp lines between the different forms that, as Rosenstein has said, one would conclude that a glance through the microscope would readily differentiate them. Charcot described:

1. *Cirrhose d'origine biliaire.*

2. *Cirrhose d'origine veineuse.*

3. *Cirrhose monocellulaire*, characterized by the presence of connective between individual cells within the lobule, seen especially in hereditary syphilis.

The French school postulates the following differentia between the two types of cirrhosis: in the

venous variety, the connective tissue and inflammation extend around several lobules, sending in connective tissue processes late, if at all, into the lobule, hence a peripylephlebitis; in the biliary type, the connective tissue begins in the lobule, around the smaller bile radicles, with increase in the biliary vessels, hence a primary angiocholitis or periangiocholitis. In the venous form, the connective tissue exerts compression upon the lobule *en masse*, hence called cirrhose multilobulaire s. annulaire; in biliary cirrhosis, the compression is in the lobule, hence denominated cirrhose insulaire s. monolobulaire. In the vulgar cirrhosis the process is extralobular; in biliary, it is extra- and intralobular. In the venous or portal type, the liver is small, ascites is present, there is no icterus and the liver cells are degenerated; in the biliary form, the liver is large, ascites and other expressions of stasis are absent, icterus is the cardinal symptom and the liver cells are intact, a pathognomonic criterion.

To my mind the differential diagnosis demands elucidation of the following points: 1, distribution of the connective tissue; 2, status of the bile ducts; 3, character of the new-formed connective tissue; 4, condition of the liver cells; 5, blood vessels; 6, size of the liver; 7, bile stasis; 8, venous stasis; 9, classification.

1. *Distribution of Connective Tissue.*—This point is the most confusing of any connected with the differential pathology. Rosenstein rejects Charcot's and Hanot's terms, "intra- and extralobular," "multi- and monolobular," and asserts that there is no cirrhosis in which there are not now some small lobules surrounded by connective tissue and again many acini surrounded by connective tissue. Both distributions may occur in a single liver. In the annular and insular forms Rosenstein finds an actual histologic differential point, and the concentric ensnaring of smaller or larger groups of lobules in typical cases of Laennec's cirrhosis are to him and Ackermann truly distinctive. In typical hypertrophic cirrhosis, the connective tissue sends out processes into and around the lobules, now surrounding an entire lobule, now only certain cell groups. Rosenstein, Kelsch and Wannebroecq certainly overdraw the situation in saying that nearly all cirrhoses are mixed types (Type mixte. of Dieulafoy<sup>20</sup> and Guiter.<sup>21</sup> See also references<sup>22, 23, 24</sup>). Orth<sup>25</sup> refuses to divide cirrhosis into different types upon the distribution of connective tissue in regard to the lobule. When said tissue seems to surround lobules, the appearance is usually accidental. The same liver may show multilobular islets, large and small monolobular islets. Regarding the relation between parenchyma and interstitium, the same specimen may show here a sharp distinction and elsewhere the connective tissue running into the lobules. Orth regards all cirrhosis as essentially the same process. Hamilton also thinks Charcot's and Gombault's views extreme.

Brieger<sup>26</sup> and Sabourin<sup>27</sup> affirm that the connective tissue begins in the hepatic vein zone. French authors find the connective tissue around the bile vessels, the veins being involved later and to a less extent. Hamilton says the secondary connective tissue bands into the lobule are more numerous in biliary than in atrophic cirrhosis.

2. *The Bile Ducts.*—In general, the French authors describe a hyperplasia of the biliary passages in biliary cirrhosis. Brieger finds in every circumscribed

connective tissue formation in the liver an increase in the bile vessels, in tuberculosis, carcinoma, adenoma, gregarinæ, distomata, and even in corset liver. Rosenstein states that he has found them (perhaps by accident) more frequently in atrophic than in biliary cirrhosis and can not, therefore, consider them pathognomonic of biliary cirrhosis; also that they sustain no causal relation to icterus. The ducts are described as filled with degenerated and desquamated epithelium and less frequently with pigment masses. Rosenstein affirms the existence of this condition in the hypertrophic cirrhosis without icterus. Ackermann<sup>28</sup> thinks the new formed bile vessels communicate with the smallest biliary vessels on the one hand, and with the main duct on the other, and gives as proof the results of artificial phosphorous cirrhosis. Orth considers the canal system as due, chiefly at least, to atrophic liver cells arranged in rows, although he admits they may in part be neoplastic. They can be infected from the biliary system and are absent in no type of cirrhosis. (Also the view of Kelsch, Kiener, Sabourin.)

Friedländer<sup>29</sup> was the first to discover this reversion of atrophic liver cells to their embryonal duct-like condition. The ducts disappear where the connective tissue is densest. According to Price<sup>30</sup> the ducts are of two kinds: 1, true bile ducts; 2, duct-like structures continuous with and imbedded in large tracts of fibro-nucleated tissue, being transformed into fibrous tissue. Small nodules on the surface are occasionally due to biliary polyadenomata.<sup>31</sup> Ziegler describes a bile vessel proliferation in all cirrhoses.

*Character of the new-formed Connective Tissue.*—Ackermann calls attention to the fact that the new-formed connective tissue in biliary cirrhosis remains uncontracted, hence the names elephantiasis hepatis (Eichhorst) and L'hypermégalie (Schachmann). In atrophic cirrhosis it is fibrous; in hypertrophic, embryonal in character (Rosenstein). Stadelmann remarks that the biliary cirrhotic liver never contracts. Orth admits that a biliary form exists, characterized by its clinical course and lack of atrophy, with the qualifying phrase that the future only can assign to biliary cirrhosis its exact status. Strümpell thinks the lack of contraction has been overestimated and that the organ would contract, were life protracted. Hamilton describes the connective tissue bands as finer in hypertrophic than in atrophic cirrhosis.

4. *Condition of the Liver Cells.*—That the liver cells preserve their form is characteristic of biliary cirrhosis. They are at most flattened only at the periphery of the lobule and may disappear. Fatty infiltration and necrosis is said to be very rare. The nuclei are preserved. The cells are sometimes pigmented or atrophied but often both cell and nucleus hypertrophy and divide. In Laennec's form the cells are often degenerated, very frequently fatty, now in the center, now in the periphery of the lobule. Hamilton says fatty degeneration is rare even in Laennec's cirrhosis, while fatty infiltration and hypertrophy occur.

5. *Condition of the Blood Vessels.*—The interlobular blood vessels in the portal cirrhosis are diseased, while free in the biliary type (Rosenstein). Ackermann's view has already been quoted (v. s.). The integrity of the hepatic or sublobular system is, according to Jaccoud,<sup>32</sup> quite exceptional.

6. *Bile Stasis (Icterus).*—Icterus dominates the clinical picture in the biliary variety. Most author-

ities admit that jaundice occurs more frequently in biliary cirrhosis, although it may be absent.<sup>33</sup> Howard found icterus in 70 per cent. of hypertrophic and 71 per cent. in atrophic cirrhosis. Mangelsdorf found icterus in thirty-eight out of forty-nine cases of hypertrophic cirrhosis. Fogge (quoted by Charcot) found it in 25 per cent. of atrophic cirrhosis (130 cases) and Rosenstein in 15 per cent. Icterus is absent in the cirrhose hypertrophique graisseuse (Sabourin). In Laennec's cirrhosis, it is incomplete, caused by compression of bile ducts by contracting connective tissue. Its frequency is variously given; seldom (Murchison, Oppolzer and Charcot); frequent (Bamberger, Leyden, Fürbringer); necessary to the diagnosis (Leyden<sup>34</sup>); slight in degree (Frerichs, Keussner); coming on before severe symptoms (Bright). In hypertrophic biliary cirrhosis some consider the icterus due to polycholia. (Rosenstein, Labadie Lagrave).

In atrophic cirrhosis, jaundice is a genuine complication, due to catarrh, glands, or a diffuse cirrhotic process (Andral, Clin. Med., 11), yet few pass through the disease without a muddy yellow areola under the eyes. In hypertrophic cirrhosis the stools remain yellow, an important point (Fürbringer, S. 121 ref. 2), yet sometimes they are acholic (Liebermeister 2). Stadelmann believes many of Charcot's cases of biliary cirrhosis were only instances of retention icterus (from calculi, cicatrices, etc.). Rosenstein has observed catarrhal icterus lasting between one and two years and has seen three cases of amyloid with icterus. In biliary cirrhosis the icterus varies directly with the fever curve and the size of the liver (Jaccoud).

7. *Venous Stasis*—is absent or inconsiderable in biliary cirrhosis, being terminal or complicating. It is present in the mixed forms (biliary plus venous). In advanced cases of atrophic cirrhosis, ascites is rarely absent, yet the patient may die before ascites develops, *e. g.*, from hemorrhage, for hemorrhage is dangerous when there is no ascites (Leyden). An extensive though slowly developing collateral circulation may permanently relieve ascites. Ascites is no infallible sequence of atrophic cirrhosis (Lecorché, Hanot). It may disappear after hemorrhage (Fauvel), diarrhea (Linas) or carcinoma of esophagus (Lecorché, Telamon). It usually antedates edema of the legs, although anasarca may appear first from: 1, renal or cardiac complications; 2, compression of inferior vena cava; 3, perihepatitis involving cava; 4, cachexia; 5, thrombosis of iliac veins. Splenic tumor is seen in both forms. Atrophic cirrhosis is accompanied by mechanical gastrointestinal stasis with hypostatic hemorrhage. In biliary cirrhosis, hemorrhage in other situations, *e. g.*, epistaxis, is more frequent. Fürbringer has, however, observed in biliary cirrhosis, hemorrhagic gastritis and enteritis. The metabolic disturbances are the same in both forms, except that alimentary glycosuria is more frequent in the atrophic. In Laennec's type, constipation is the rule; in biliary, diarrhea. In both, dilatation of the right ventricle, leucocytosis, remittent or intermittent temperature occur. Tubercular peritonitis and granular kidneys are common in the atrophic form, while rare in the biliary. In biliary cirrhosis, albuminuria is infrequent while a high pulse rate and a terminal cholemic condition are usual.

## CLASSIFICATION.

I suggest the following classification, less as an arbitrary or infallible scheme than as an attempted tentative reconciliation of conflicting clinical and pathological data awaiting stricter future analysis:

Cirrhosis hepatis.	I. Capsular.	{ a. Chronic perihepatitis. b. Portal vein syphilis.
	II. Vascular	{ a. Hepatic vein. b. Portal vein.
	III. Biliary.	{ a. Obstruction—"Retentions-icterus" and cirrhosis. b. Biliary or hypertrophic, in French sense. IIa- not's cirrhosis. (Vascular and biliary cirrhosis.)
	IV. Mixed.

## HYPERTROPHIC CIRRHOSIS OF THE LIVER WITH JAUNDICE.

Read before the Chicago Pathological Society, Feb. 11, 1895.

BY T. J. WILLIAMS, M.D.

HOUSE PHYSICIAN COOK COUNTY HOSPITAL, CHICAGO.

The patient who died of this affection at the County Hospital last January, was a white woman of Irish extraction, 40 years old, married, having several living healthy children, and an exceptionally good family history. She had malaria and rheumatism several years ago but neither of these confined her to her bed, and she considered that she had had unusually good health up to one year before she came into the hospital, when she first noticed a dull heavy pain in her right side, about the border of her ribs, and became jaundiced. But all the symptoms of this attack passed away without any treatment, and she felt fairly well except for occasional vomiting spells, until toward the end of November, when she was again attacked with the same dull pain in the region of the liver and became yellow.

December 21, she came to the hospital and stated that she had been sick for five weeks; she complained of pain and tenderness in her right side, but was most concerned about the yellowness of her skin and a tumor of which she had lately become conscious in

her abdomen. Her temperature on admission was 100.8, her pulse 106 and respiration 32. She did not appear to be very sick. She was extremely stout and apparently suffered no pain. She recited her history intelligently, appeared to have been a virtuous woman not addicted to drink, and free from any venereal history. Her skin and conjunctiva were yellow, at first not very marked, but became extremely so toward the end—otherwise her skin and eyes were negative, but she complained as she grew worse that her sight was getting poor, and some time before death had diplopia. Her breathing was accelerated and shallow; her pulse weak, and rather rapid, but neither lungs nor heart gave any other sign of disease. Her abdomen was very prominent but symmetrical. The tumor of which she complained was easily palpable. Its smooth, rather sharp edge, could be felt in the median line running down into the right iliac region. Slight pressure upon it caused pain. Owing to intestinal tympany, and a very thick layer of fat overlying it, the spleen could not be palpated or percussed. No fluid could be shown to be in the peritoneal cavity, and there were no enlarged abdominal veins although there was some edema of lower limbs. She gave no history of any pelvic trouble except profuse menses during last two periods before admission and there was no tenderness over the pelvic viscera. As the jaundice deepened, she complained of a "dead feeling" in her arms and legs which became very weak, and later, she had "drop wrist" of both arms and complete paralysis of lower limbs. Her intellect became dulled. She was occasionally delirious, but control of the bladder and rectum was retained to the end. There was at no time any gastric disturbance; she retained her food and medicine well, but her bowels were extremely constipated and would not respond to any but strong cathartics. Her urine at no time contained any albumin or sugar. It was generally of a low specific gravity, acid reaction, dark color, and gave a marked biliary reaction. Her pulse was not at any time slow, generally between 90 and 110. Her temperature varied between 98 and 102 until immediately before death it went to 103.4. For about forty-eight hours before death she was stupid and semi-comatose and died four hours after the onset of deep coma.

A post-mortem examination of the body was made twenty-four hours after death occurred. There were no scars, eruptions or ecchymosa on the body but the skin was intensely yellow. There had been no emaciation. The abdominal wall contained 32 cm. of fat at the umbilicus. There was no fluid in either pericardial or pleural cavities. The heart was covered almost everywhere with fat. It was empty, weighed 550 gms., and was so flaccid that when held by the great vessels, with its base upward, it fell like a mushroom over one's fist. There was neither incompetency nor stenosis of any value. The cavities of the heart and the thickness of its walls, were of normal dimensions. The aorta at its beginning had a few soft, small, whitish-yellow atheromatous patches—but nowhere else was there found any arterial degeneration. Both lungs were negative, except that considerable blood and mucus could be expressed out of the lower lobes on both sides, but sections of these would crepitate and float. The pleural cavity on the right, contained many firm adhesions while there were a few stringy bands also on the left. The peritoneal cavity contained a few ounces of fatty serous fluid.

Pushing them aside the intestines disclosed the right lobe of the liver running from the crest of the ilium with its left edge in the median line and reaching the lower border of the third rib above. While the left lobe reached about 2½ cm., below and to the left of the tip of the sternum, and was adherent to the spleen, the hypertrophy was seen to be mainly in the right lobe. The common bile duct was patent. The gall bladder was of ordinary size but rather thick, and contained some thick, syrupy brownish-yellow liquid which could be expressed into the duodenum with very slight pressure. The liver weighed 4,150 gms., its right lobe measured 33 cm., from above downward, 23 cm. laterally, and was 18 cm. thick. Its surface was smooth, mottled, brownish-red and light yellow. On anterior part of right lobe was a thickening of the capsule indicated by a small whitish area with white lines radiating short distances from it. A cut section appeared yellow, being deeply bile stained; its surface felt rough; the lobules could be distinguished only by a slight elevation of their border. The spleen was adherent to the stomach, diaphragm and left lobe of the liver. The capsule was torn in an effort to detach it and its pulp substance, was so diffuent, while the trabeculae were extremely friable, that its contents escaped into the peritoneal cavity. The spleen reached about two inches below the costal arch, and up to the upper border of fifth rib. Both kidneys were enlarged. The capsule of each peeled readily, leaving a smooth surface. The cortical markings were indistinct in each, while the pyramids were dark in contrast to the somewhat pale cortex. They were bile stained like all the other visceral organs and weighed together 560 gms.

The pelvic organs were matted together by old adhesions into one solid mass; the left Fallopian tube, which had extremely thick walls, contained a few drops of inspissated whitish pus. The meninges were negative, as was also the surface of the brain which was not dissected. Nothing abnormal was found in the alimentary tract. Sections of the liver hardened and stained with hematoxylin and eosin and examined microscopically show that the lobular outlines are indistinct, and that while there is some increase of interlobular connective tissue it is not nearly as marked as in any ordinary form of atrophic cirrhosis. There is marked increase of this tissue within the lobules. In some it runs at right angles to the periphery from the center, disposing the cells radiating in rows from the center; in others it is arranged in circles, so that the cells are arranged in layers concentric to the periphery, at the outer parts of the lobule. This latter distribution seems more common than the former. In a few lobules the connective tissue is irregularly distributed so that they are made up of isolated groups of cells. With a 1½ inch oil immersion objective this connective tissue is seen to be made up of a highly refractive, hyalin-appearing substance containing a few spindle-shaped nuclei and, as a rule, stains well with eosin. This connective tissue is best seen in areas where marked fatty degeneration has taken place. Here it is almost transparent and does not take eosin well. The cells of Kuppfer, marking the position of the blood capillaries, are infrequent.

The most marked increase of connective tissue is seen where sections of bile ducts are obtained. Here there are broad bands that stain well with eosin, and

contain many spindle cells with long pointed ends. The bile-duct epithelium stains very deeply everywhere. There seems to be an excess of bile ducts only in a few places. The increase in connective tissue is more marked around the ducts than around the hepatic or portal veins, and it is more hyalin in character around the ducts.

The liver cells show marked signs of two kinds of degeneration, a fatty and a hyalin degeneration. The first should perhaps be called a fatty infiltration, because in the cells which are occupied by the holes left after the fat had been dissolved out, the nucleus remains well stained in the periphery, while the circular vacuole is partially surrounded by a narrow rim of cell protoplasm. This fatty infiltration affects all the lobules, more or less, and is so marked in some places that but a few cells are left.

Where the hyalin degeneration occurs, the cells stain very poorly even with eosin, the nucleus appears faint or not at all. There is no nuclear pigmentation. Some of the cells contain a golden yellow pigment, which appears a yellowish brown where the granules are large. Some lobules are occupied entirely by this degeneration, while in other lobules it is mixed with the fatty infiltration. It is everywhere most marked in the periphery of the lobules. In places this degeneration appears to have been caused by deposition of pigment; in other places it seems to be due to the fine connective tissue network which isolates groups of cells from the rest of the lobule.

The liver cells which stain well often possess two nuclei. In some, these lie close together upon the same plane, but no connecting bands indicating karyokinesis can be made out. While some of the cells appear larger than normal, no measurements have been made. Some areas are seen which show hemorrhage, but they are small and infrequent and resemble spots of red atrophy. In still other places, there are spots of leucocytosis. This occurs usually in areas of marked degeneration where liver cells have entirely disappeared, leaving only a network.

The microscopic examination was made in the laboratory of Rush Medical College, under the direction of Mr. E. R. Le Count, to whom I am indebted for valuable aid.

#### DISCUSSION.

DR. E. R. LE COUNT—I was very much interested in Dr. Edwards' paper in which he gives the views of the various authorities upon different forms of cirrhosis, and we know there is a great conflict of opinion in regard to this matter. The opinion of Rosenstein, which he mentions as having been advanced in the Congress of Internal Medicine, held at Leipsic, in 1892, of dividing cirrhosis into the atrophic form, the hypertrophic form with icterus, and the hypertrophic form without icterus, in which the latter is associated with the formation of connective tissue atrophy, is the most rational division that can be made. The liver is possessed of a great degree of power to regenerate itself, and experimental investigations upon animals have shown that this power is possessed by it to such an extent that an entire lobe may be regenerated. It is this property of regeneration that has given rise to so much discussion as regards the forms of cirrhosis. In this division of Rosenstein; the hypertrophic with icterus, and the atrophic and hypertrophic without icterus, in the use of the term biliary, with cirrhosis, it must not be forgotten that biliary cirrhosis may be atrophic in many cases, as was mentioned in the statistics given by Dr. Edwards. In most of these cases of biliary atrophic cirrhosis there is chronic obstruction of the gall duct, and the atrophy of the liver is secondary to the obstruction of the gall

duct. In biliary hypertrophic cirrhosis, obstruction does not usually occur, but it does take place in the biliary atrophic form by gall stones very frequently. I have had the opportunity of looking over the specimen presented by Dr. Williams, and the peculiar feature is that it is complicated with degeneration, which does not usually occur in hypertrophic cirrhosis. But in this instance the fatty degeneration is to be regarded—at least, so far as the microscopic appearance goes—as an evidence of a conservative process. At no point could vacuoles be made out which resemble those seen in cases where the liver cells undergo metamorphosis. In regard to the other form of degeneration, the word amyloid is as applicable as any term that could be used. The test for amyloid material was not made in this case to my knowledge.

DR. JOSEPH M. PATTON—These two very interesting and complete reports, together with the discussion so far, serve to illustrate the confusion that exists in regard to the pathology of the different forms of cirrhosis of the liver. As Dr. Edwards has stated, there is a marked difference of opinion entertained by the French and German school. When we have gone over the various reports regarding this subject, we are so inextricably confused that it is difficult to make out anything in regard to the present status of the question. It seems to me, that clinically and in a gross pathologic way, we can certainly make out that we have an atrophic form of cirrhosis of the liver, which clinically is not as a rule accompanied with jaundice, but which may be so; and that we have an hypertrophic form or an enlarged liver which is cirrhotic, which is more apt to be accompanied with jaundice and in which cirrhotic processes are most likely to be found beginning in and around the biliary duct. Clinically, it is very difficult to make out, when you first see a case which of those two forms it may be. If a man does not believe in the hypertrophic stage of the ordinary atrophic liver, he would not be puzzled, but the consensus of opinion is in favor of such a stage, and personally I am satisfied that I have seen two or three cases in this stage in which the liver was enlarged and which afterward developed a typical hob-nail liver. This does not always occur, and it is not an easy matter to make out this stage because those cases comparatively seldom come under our observation during the enlargement of the organ.

DR. R. H. BABCOCK—One point of clinical interest is this: we ordinarily suppose that an atrophic cirrhosis of the liver means a liver smaller than one of normal size. We certainly do observe, clinically, cases of liver which, after having been of abnormal size from passive congestion for years, undergo contraction and hardening without coming down to a size less than a normal liver, and unless I am mistaken—and if I am in error I wish some of the pathologists present would correct me—such a liver is an instance of atrophic cirrhosis, although not Laennec's atrophic cirrhosis. I have in mind two cases of mitral disease in both of whom the livers are larger than normal, extending some inches below the inferior edge of the ribs. In these cases the livers are very firm, hard, and with a sharp grisly inferior edge. One of the patients has been under my observation since September, 1886, and the liver when I first saw the case was apparently simply one of passive congestion. The inferior edge presented a rather rounded border, and there was tenderness. That liver has since contracted, and all of the symptoms of which the patient complained during the state of congestion have passed away. Her liver reaches nearly the level of the umbilicus. Is not this a case of atrophic cirrhosis of the liver in which the organ is larger than normal?

DR. EDWARDS—The reason that I brought out the conflicting opinions of the different authorities on the subject was to show how one, in searching for definite criteria to differentiate between the two cirrhoses would be unsatisfied, because there is scarcely a single criterion given for one type that may not be found in the other. The second point, and one that I would like to have heard discussed in connection with the case reported, was the almost exact parallelism between the clinical questions which came up in respect to our case and the pathologic findings; that is to say, the difficulties which we encounter clinically are insignificant to those which we find on gross pathologic inspection, or even under the microscope.

DR. WILLIAMS—It seems to me as if the differential diagnosis between many cases depends more upon clinical than microscopic evidences. We may get cases of hypertrophic cirrhosis with a considerable difference between them microscopically, and I would rather agree with the observations made by some French writers, that the disease can be called hypertrophic cirrhosis with jaundice, if we have

an enlarged smooth liver and enlarged spleen with jaundice and without ascites, where carcinoma, echinococcus cysts, and other causes of enlargement of the liver can be excluded, irrespective of the distribution of the connective tissue or the presence of degeneration of the liver cells.

## SERO-THERAPY AND ACCESSORY TREATMENTS OF TUBERCULOSIS.

Read before a "Tri-State" Medical Society, April 21, 1895, St. Louis, Mo.

BY PAUL PAQUIN, M.D.

PHYSICIAN-IN-CHIEF OF THE ST. LOUIS SANITARIUM FOR THROAT AND LUNG DISEASES, ST. LOUIS, MO.

In January last I had the honor to report to the St. Louis Medical Society, the result of my researches up to that time, on the action of a certain kind of serum in the treatment of tuberculosis. The clinical history of twenty-five cases treated six weeks or three months was given. Seven cases (four with cavities, among whom two had been bed-ridden and given up as absolutely hopeless), were brought to the Medical Society at night, in a weather rendered severe by the fall of a melting snow, and not one coughed during the two hours of their exhibition in a smoky room. It was then demonstrated that all of the twenty-five patients had been decidedly benefited; the least that had been done for a few of them was the arrest of the decline. Only four or five were benefited to this slight degree, while all the others, all in the last part of the second or in the third stage of pulmonary consumption, were improved to a marked degree in almost every respect. Chief among the good results was the universal gain in weight, which ranged from one and a half pounds in two weeks in people who had been losing twice as much per week, to twenty-three pounds in two months; this, in spite of the decidedly meager fare that is naturally granted in the City Hospital and Poor-house. Since then, I may add that the improvement in the city cases has continued, notwithstanding the most severe tests and serious interferences, such as the repeated sulphur fumigations for several weeks during the smallpox epidemic (a test too hard even for healthy lungs); and such as the efforts that were made almost daily to produce a mental feeling against the treatment.

Furthermore, I am glad to report good results obtained since then in three private cases: Mrs. R., Mrs. V. and Mr. P., all in the second stage of the disease, whose symptoms have disappeared to such a degree that one is tempted to call them cured. That report was a statement of facts indisputable, but the facts were not accounted for, nor did the profession at home, generally speaking, view them with absolute confidence. On the contrary, although any physician could have verified the report by visits to, and study of the patients, some usually wise doctors concluded that the facts brought out must be considered impossible any way, whatever the evidence, and must therefore be discredited. But the patients still live and are still improving, and again the verification of the report then made, and to-day reaffirmed, is invited. Any physician or other individual, whom the Superintendent of the City Hospital may welcome, may go and judge for himself.

To-day I have the honor to present to this scientific body a theory explaining to a limited degree the basis of the therapeutic action of the serum and, furthermore, the grounds for, and the kind of accessory treatment that should be practiced in tuberculosis.

In the first place, we must realize that sero-therapy is not medication in the usual acceptance of the word. It is not the production of pure chemic effects as by drugs; it is the production of certain phenomena by the increase of quality or virtue of pre-existing physiologic functions, and perhaps, the creation at times, of physiologic faculties unknown before in the diseased organism. In other words, sero-therapy, the use of nuclein and other organic extracts of the kind, whether animal or vegetable, produce good therapeutic results in certain conditions, probably because they augment or create natural defensive physiologic forces necessary to fight disease.

And what does this antipathologic power depend on? It depends on the individual and collective energies and faculties of the cells, which form the ultimate appreciable structure of such complex organisms as man, and other multicellular beings.

In infections, at least, we should no longer "dope" man as a *whole*, to cure him, but we should strive to interpret the nature of the cells forming his tissues; their activities, their reactions to drugs and physical treatment, and we should minister to these microscopic individuals or aggregations, with a view to increase their natural functions in the prevention of diseases, or create activities of this character.

Sero-therapy in tuberculosis has produced the effects stated in my first report. How did it do it? By what mode of action can the serum of the blood of a horse rendered, by certain methods, more strongly immune against tuberculosis than it is naturally, arrest the tuberculous process in an infected human being? It is, in my judgment, on the one hand by an infusion in man's system of a certain quantity of the protective or defensive substances secreted naturally by the cells of the horse and during the process of immunization, the property of which is to protect this animal against the disease; on the other hand, it is probably by the action of the nuclein of the serum, which stimulates the cells of a human body to greater physiologic action against the germs of tuberculosis. It is, in a word, a form of germicidal nutrition of double value obtained by a physiologic process.

Many objections have been raised against sero-therapy by those who prefer polypharmacy (which is so convenient and presupposes no great knowledge of physiology or pathology, or anything else to practice medicine). This was to be expected.

It is a great trial for the retardative doctor in the scientific procession of medical men, this physiologic therapeutics. It is a very inconvenient thing to find one's self in the presence of the awful necessity of studying man seriously through a microscope, and to know one's self incompetent to do it. But this is the situation. Prate as we may against scientific medicine, microscopy, bacteriology, we must acknowledge that only through such, and the application of scientific facts in practice, can medicine become a science exact enough to make the doctor know and trust medicaments in a given disease. Clinical observations are invaluable as indications, and they often suffice to point to useful therapeutics, but observations alone explain nothing, and give us little data to rely upon with confidence and safety. But I am digressing. I will say that so far the objections mildly raised by the timid, wildly painted by the fearful, foolishly decried by the ignoramus,

have not materialized. Neither glanders, nor any other awful disease of the horse, in the three years of experimentation with serum, abroad or in this country, has been transmitted to man. True, a death or two have been attributed to the serum in the treatment of diphtheria, but what if it is true? What valuable, active medical agent has not caused one death in five thousand treated, or per ten thousand doses?

For my part, I can say that over three thousand injections of serum produced under my direction, have been made in human beings, and not a serious accident has resulted. In six different injections there resulted a quick disturbance of the capillary circulation, evidenced by a flush of the face, dizziness and weakness. These lasted but a few seconds, but in two instances were followed by rigors. In a few cases in which the injections were begun with large doses, 1 or 2 drachms, and pushed energetically, there followed a mild urticaria, which promptly disappeared soon after the injections were dropped or reduced, and did not reappear during the progressive dosage which followed in nearly every case.

These annoyances (produced chiefly during experimentation) are insignificant when we consider the hopelessness, the fatality of tuberculosis under any and all forms of treatment heretofore employed. The risk of one fatal result per cent. would be justifiable, if not indeed a larger proportion.

But because sero-therapy does produce a physiologic effect that tends to arrest tuberculosis, it does not follow that a physician should depend on that alone, in all forms and in any stage of consumption, and expect a cure. For one thing, it is preposterous to expect a decomposed lung to be restored by any form of therapy. It is not easier to reconstruct a pair of degenerated lungs than it would be to replace a gangrenous limb by any method. Consequently, the disease must always be diagnosed with scrupulous care, not only to establish the existence of the malady, but its particular nature, its extent, its relations to any and all of the various important organs of the body. In women the relation of tuberculosis to ovarian and uterine affections, should always be carefully considered. There are besides, the mixed infections to consider—we meet them daily. The lungs, the intestine, the liver, become the seat of myriads of germs of different kinds sometimes, and tuberculosis is then a complicated disease deadlier and more rebellious than in the most virulent form uncomplicated. What, then, should be the treatment of tuberculosis? Generally speaking, so far as the constitution goes, it should be cellular, and locally it should be antiseptic. Taking as a type, pulmonary consumption, it is necessary on the one hand to try and force the cells of the diseased to produce the greatest amount of defensive energy in whatever form nature may exhibit it. This may be accomplished presumably by sero-therapy, and may be assisted by nuclein, etc. On the other hand, we must invariably insist on the constant use of reliable non-poisonous antiseptics. This may be considered secondary to the main treatment, but in fact it is of the greatest importance. It is directed to the specific and complicating germs themselves, and aims to arrest their development.

The continual re-infection in tuberculosis, both by swallowing sputa and by the cumulative growth of the specific germs and various others, and the pro-

gressive alterations of tissue in the diseased parts can be somewhat checked by a proper direct medication, and thereby cellular constitutional remedies are given better opportunities to act.

Among the oldest forms of lung medication, is the inhalation of medicated vapors or atomized drugs. The method is good, but unfortunately it falls far short of the object sought, chiefly, because the inhalations are not constant enough for one thing, and, on the other hand, the antiseptics selected are seldom well chosen. Inhalation, to produce useful, lasting, germicidal effects, must be almost continuous. During a long period of experiments, I have tried the various inhalers on the market, but none filled the want in my judgment. What we need is an apparatus that will atomize or vaporize eight or twelve or more hours continuously, at a slight expense. After numerous experiments and tests, the vaporizer here exhibited was produced. It is not yet perfect, but needs only slight improvements to make it what is desired. It will throw a spray all night and all day at the cost of a few cents of alcohol, and will keep the air of a room filled with antiseptic material.

Beside this, a mouth-piece attached to the nozzle can be made to direct the vapor straight to the nose and mouth from the bedside.

Another thing useful for disinfection in tuberculosis, is this "lip-trough-inhaler" for essential oils. It is fitted under the nose, and the ribbons are tied behind the head. Before putting it on, a little bundle of absorbent cotton, or a little sponge is placed in the trough and a few minims of the essential oils selected are dropped on the cotton twice or three times in the twenty-four hours. This may be worn almost constantly. I devised this little instrument to carry out the idea of Carasso, who prescribed with great benefit, essence of peppermint on a little cotton wad placed under the nose.

In conclusion, let me speak of two other very serious necessities in the treatment of consumption: I refer, first to nutrition, which may be forced and should always be guarded and wisely directed—of this I need not speak here. I will only say that in cases of mal-nutrition in tuberculosis, some easily

<sup>1</sup> Manufactured and owned by the firm of Holekamp-Moore, instrument makers, St. Louis, Mo.

digested and very nutritious aliments must sometimes be used. Mellin's Food has served me a very good purpose in many cases; I prescribe it often, and the various liquid peptonoids have materially assisted me.

I refer secondly to repeated disinfections of the mouth. The mouth and throat should be frequently gargled with a strong non-irritant antiseptic preparation. This is demanded both for the protection of the patient against infection of the throat, which is not uncommon as a secondary process, and for the protection of relatives, friends and the public, because through kisses and the saliva expectorated, the germs are carried to others. The writer has tried numerous ingredients for this purpose, but was disappointed more or less, or dissatisfied in one way or another, with everything tried. Citric acid, and most of the essential oils are good, but unfortunately they are not easily combined over the prescription counter. In the last few months I have tested and used Pasteurine very largely, and found it just what seemed desirable. Its antiseptic effects are strong, and yet there results no irritation. The preparation is exceedingly pleasant to the taste and is very fragrant. I use nothing else now.

I here append a few formulas which I use for direct antiseptic medication in tuberculosis of the respiratory organs:

R Creasote (beech-wood) or trikresol.....4 oz.  
 Pasteurine .....8 oz.

⚗ Sig: A large tablespoonful per pint of water. Vaporize in the "Continuous Siphon Vaporizer."

R Carbolic Acid ..... ½ dram.  
 Pasteurine .....8 oz.

⚗ Sig: Use as a mouth wash and gargle three or four times a day.

R Ess. oil of peppermint (chem. pure).....1½ oz.  
 Ess. oil of eucalyptus (Tyndale's) ..... ½ oz.  
 Ess. oil of cinnamon (chem. pure)..... ½ oz.

⚗ Sig: Two to five drops on cotton or sponge in "Lip-Trough-Inhaler," three or four times a day.

### PROTECTOR FOR THE HAND IN INTUBATING THE LARYNX.

BY JOHN EDWIN RHODES, A.M., M.D.  
 PROFESSOR OF PHYSICAL DIAGNOSIS AND CLINICAL MEDICINE NORTH-WESTERN UNIVERSITY WOMAN'S MEDICAL SCHOOL; LECTURER ON LARYNGOLOGY AND DISEASES OF THE CHEST, RUSH MEDICAL COLLEGE, ETC., CHICAGO.

One of the great dangers attending the operation of intubation, is that of injury to the hand of the operator, while introducing or extracting the tube.

I have employed a number of devices for the protection of the hand and finger. Sometimes a heavy rubber cot, cut off at the closed end, and drawn well

over the finger will answer the purpose with a very young child. With older children, protection for the finger alone is not sufficient, and lately, I have wrapped a piece of adhesive plaster about 4 or 5 centimeters in width about the knuckle of the index finger, as suggested to me by Dr. John Bartlett. This does very well, but takes time, and is not always obtainable.

The protection of the knuckle and hand are necessary because the larynx is sometimes so far from the lips that, in order to carry the tip of the finger into it, the knuckle is pressed against the upper teeth so forcibly that a contusion or laceration of the skin may be caused, unless great care is exercised. In the hurry incident to this operation, which requires dexterity and often great celerity, some precautions are apt to be neglected, and the dangers resulting from a wound which might be received in this way are forgotten.

I have devised the protector, believing that it meets all the requirements for which it is designed, in the operation. It can be carried in the intubation case, is easily and quickly adjusted, it can be easily cleansed and disinfected, is flexible and does not hamper the movements of the hand or finger. It affords perfect protection to the forefinger and the plantar and palmar surfaces of the hand, so that injury by the teeth of the patient either from biting or from the chance slipping of the gag, (an accident which often occurs), or from forcible pressure against the upper teeth in reaching the larynx is impossible.

Messrs. Sharp & Smith, 73 Randolph Street, Chicago, have made these protectors for me in two sizes, so that the hand of any operator may be fitted. They are made of the best rubber, 1½ millimeters in thickness.

Venetian Building, Chicago.

### SOCIETY PROCEEDINGS.

#### Association of American Physicians.

Tenth Annual Meeting held at the Army Medical Museum and Library in Washington, D. C., May 30 and 31, 1895.

[Special correspondence of the JOURNAL.]

FIRST DAY, THURSDAY, MAY 30.

The meeting was called to order by Dr. WILLIAM OSLER, who delivered the President's Address, in which he asked how far the Association had fulfilled the object which it had in view at its beginning, and if the aspirations and hopes had been realized in the advancement of scientific medicine. This was an organization with no code of ethics, no medical politics; no one cared who were the officers and who not. It was not asked from what part of the country a member came, but has he done good work, and still more, if he has anything worth saying and can he say it? Nine volumes of transactions show what has been done. Some of the most noteworthy papers of the past ten years have been brought to light before this Association and all the questions of the

day have been discussed. The classical work of Fitz and Draper has been brought before the Association and in the discussions such subjects as the diagnosis of diseases of the stomach, of the pancreas, dysentery, infarction and other affections of the bowels, heart disease, sclerosis of the arteries, the mutual relation of renal, arterial and cardiac changes, anemia and chlorosis, thrombosis in chlorosis, myxedema treated with thyroid extract, removal of the ovaries and tubes, subphrenic abscess, acromegaly and lead poisoning had all been discussed. Dr. Osler said: "Our Association has had already a potent influence on the study of pathology and clinical medicine in this country. We need, however, a larger growth of men who are devoting themselves exclusively to these branches. The rapid progress of the medical schools has increased the number of teaching positions in the scientific branches and there is at present an actual scarcity of well-trained pathologists and bacteriologists to fill them. There is no need to insist upon the necessity of accurate and careful training in the development of workers in these branches. I do not think the profession of this country understands as yet the art of training special clinical physicians. They have taken too much for granted that such men develop readily in the routine of family practice. True, along this path some of the most noted men of our ranks have traveled, but the time has come when able young men should be encouraged to devote themselves to internal medicine as a specialty, content to labor and wait during the first ten or fifteen years of professional life with pathology as the solid basis of development. Such men will pass to the wards, through the laboratories, thoroughly equipped to study the many problems of clinical medicine; they will gain the confidence of their professional brethren by their accuracy and skill, and through them they will reach the public and a large practice. Such an opportunity and career is within the reach of every physician in any city with a hospital of fifty beds."

Dr. Osler then referred to the members who had died, and mentioned especially Drs. Alfred L. Loomis, of New York, and William C. Dabney, of the University of Virginia.

Dr. B. K. RACHFORD, of Cincinnati, then read a paper on

#### LEUCOMAINE POISONING,

in which he said that leucomaine poisoning showed itself: 1, as a true migraine of leucomaine headache; 2, as a migrainous epilepsy or leucomaine epilepsy; and 3, as a migrainous neurosis or leucomaine gastric neurosis. We know very little about these substances. The principle ones are xanthin and paraxanthin and they were described by Salomon, of Berlin, who has done the best work on this, and he laid down the following points:

1. Paraxanthin and xanthin are poisonous leucomaines of the intestinal acid group, capable of producing the most pronounced nervous symptoms. They are readily soluble in water, urine and blood.

2. Paraxanthin is present in normal urine in such small quantities that its poisonous properties are lost in the solution.

3. Paraxanthin and xanthin are not found in the kidney; they are excreted from the blood by the kidneys.

In normal urine it takes about 9 liters to prove the presence of paraxanthin, and when we find it in 4 liters it is abnormal. Migrain is the most common manifestation of xanthin poisoning. In one case he found it in 3 liters of urine and in another case in 2 liters. It is recognized by the needle crystals and by its physiologic effects on animals. It could not be found between the attacks, which shows that it is excreted in disease during the attacks but not between them. In migrainous epilepsy the characteristic symptoms are: 1, the sudden onset of the attack, as a rule without warning; 2, the muscles are rigid but not convulsed; 3, labored, gasping and irregular breathing; 4, unconsciousness from the beginning to the end of the attack; and 5, the heart's action is rapid but regular and strong. In the study of migrainous epilepsy the following summary of facts may be made:

1. Uric acid and its compounds are not poisonous.

2. Paraxanthin and xanthin are poisonous leucomaines of the uric acid group which when injected into the mouse produce the following symptoms: (a), nervousness, extreme reflex excitability, almost tetanus and at times convulsive movements; (b), clonic tetanic stiffening of all the muscles followed by muscular relaxation; (c), dyspnea, orthopnea, asphyxia, gasping and difficult respiration is perhaps the most characteristic symptom; (d), stimulation of the heart, its movement marked and strong.

3. The patient during the intervals between the attacks

did not excrete sufficient paraxanthin to be detected in 4 liters of urine.

4. The patient during an attack excreted a quantity of paraxanthin and xanthin enormously in excess of the normal amount. The paraxanthin thus excreted obtained from 3 liters of urine produced in the mouse and rat the characteristic symptoms of paraxanthin poisoning and abdominal enlargement.

5. The attacks during and after which the patient excreted such large quantities of paraxanthin were very similar to the paraxanthin poisoning in the mouse.

6. The paraxanthin excreted in such large quantities just following this attack must have been in solution in the blood during the epilepsy. In his experiments on animals he found that the permanganate of potash acted as an antidote to the leucomaine poisoning and for this reason he gave it to his patient with epilepsy, with some good to her, and she still takes it and has not been able to do without it for longer than six weeks at a time. He also reported one case of migrainous gastric neurosis in which there was vomiting relieved only by morphia, increased quantity of uric acid, xanthin and paraxanthin in the urine. He made the following points:

1. He found a history of migraine.

2. Previous personal history of sick headache.

3. The patient now suffers from attacks of severe gastric neurosis which recur at intervals of two or three weeks.

4. In 4 liters of urine excreted by the patient, in the interval between the attacks no paraxanthin was found and the "final fluid" was not poisonous to mice.

5. In 2 liters of urine passed by the patient during an attack, both paraxanthin and xanthin were present in comparatively large quantities and the "final fluid" was especially poisonous to mice.

6. From about one pint of stomach contents vomited by this patient during an attack, xanthin was separated but no paraxanthin was found. We can thus recognize three clinical types of leucomaine poisoning: (a), leucomaine headache; (b), leucomaine epilepsy, and (c), leucomaine gastric neurosis.

Dr. F. P. KINNICUTT, of New York, asked if he had examined the urine of tetanus patients. It is probable that a certain number of these cases of tetanus are due to this. In cases of disordered stomach, especially gastro-intestinal disturbances, an examination might throw some light. He has seen two cases of tetanus, one fatal in forty-eight hours, in which the autopsy showed an enormously dilated stomach. The patient had had several previous attacks.

Dr. W. H. THOMSON, of New York, was much gratified at this paper. He has long held this view. Cases of functional neurosis are not nervous disease at all, but are due to toxins rather than to gastric disease. He had had success with the benzoates of sodium and ammonium. Some of these cases occur in groups and develop these nervous symptoms only now and then. Heredity plays an important part here.

Dr. F. C. SHATTUCK, of Boston, asked how long it took to make these chemic examinations of the urine. He asked because he once had such a case and it took four weeks.

Dr. J. E. GRAHAM, of Toronto, asked if he had made examinations of the urine shortly before an attack.

Dr. RACHFORD said that in his cases he took usually about three weeks to make an examination, and he has made these examinations at almost all times, and one week before an attack he had failed to find them. He had thought of tetanus but had not had a suitable case since he began this work. The subject has an important bearing on uremia and allied conditions.

Dr. A. C. ABBOTT, of Philadelphia, then read a paper on the "Effects of the Gaseous Products of Decomposition upon the Health and Resistance to Infection of Certain Animals that are forced to respire them." He put animals under a bell jar and compelled them to breathe air from decomposing substances and even inoculated some of them with the typhoid bacillus culture and found that the general results were negative; the animals did as well as others not experimented on, and he thought that such air has not the power of inducing pathologic conditions, or if it has, it has not been shown.

Dr. C. BAUMGARTEN, of St. Louis, then read a paper "Renal Affections following Influenza." The question is of great interest. The origin of many cases of nephritis is very obscure, but the study has narrowed down this subject and simplified it. Influenza is one cause not generally recognized. Many authorities are silent on this subject and little mention is made of it in medical literature. It occurs more

frequently than is supposed. Damage to the kidney is a frequent, certainly serious result of the grip. Besides transient albuminuria, there have been found acute degeneration of the kidney, acute inflammation, both forms of chronic diffuse nephritis and cases of persistent albuminuria not plainly belonging to one of these groups. The damage to the kidney does not usually show itself until the influenza is forgotten. This has been shown in life insurance examination statistics. In the five years preceding the grip, he had found but about 1 per cent. of albuminuria among the cases he examined but in the next five years after he found 3½ per cent.

DR. A. JACOBI of New York, had found this sequel frequently. The diagnosis was made possible by the use of the centrifuge and many cases would have escaped notice but for this instrument. It is the same kind of albuminuria as after diphtheria and typhoid fever and it must also be caused by a toxin of the germs causing those diseases. It is not like the post-scarlatinal nephritis. The large majority of cases get well in two or three weeks or a month but a few become chronic.

DR. JAMES TYSON of Philadelphia, had seen several such cases, and he found that persons who had a physiologic albuminuria were always worse after grip.

DR. F. C. SHATTUCK of Boston, had seen a number of these cases. In one autopsy he had found a large red swollen kidney. He did not believe the condition was the same after each disease. He does not recall a case following typhoid fever as that after other diseases.

DR. M. H. FUSSELL of Philadelphia, has discovered so many of these cases that he never regretted his rule to make a routine examination of the urine in all cases without exception.

DR. JACOBI said he had referred to the kidney complication during and not after typhoid fever.

DR. A. H. SMITH of New York, said that this complication was much more frequent than was usually supposed, and those we recognized probably represented a small part of what actually occurred. Subnormal temperature is one symptom due to profound poisoning of the nervous system; it is much more severe than the primary poisoning from the grip.

DR. BAUMGARTEN said in conclusion that we must distinguish between those complications of the kidney that came on during, and those that came on after the grip; those with or without dropsy, those with uremic symptoms and other troubles which can probably be traced to this devastating disease.

DR. GEORGE M. STERNBERG, Surgeon-General, U. S. A., then presented a paper prepared by himself and Dr. Walter Reed, Surgeon, U. S. A., on "Immunity against Vaccination Conferred upon the Monkey by the Use of the Serum of the Vaccinated Calf and Monkey." They succeeded in establishing immunity in the American monkey for thirty days, but the result did not reach a practical conclusion because the amount of serum to neutralize the poison of the disease was too large for a dose, being about 1 to 100 to 1 to 50 per body weight.

DR. JAMES T. WHITTAKER of Cincinnati, then read a paper on the "Etiology of Idiopathic Hypertrophy of the Heart." He did not refer to enlargement due to valvular disease. The term idiopathic, is a misnomer. In some cases the cause remains concealed and it is called cryptogenetic. It is not a rare disease and may occur after severe strain as after war. There is a change in the position of the apex. The diagnosis may be made without the aid of percussion. The attempt to make out the triangle of the heart dullness by percussion is difficult. Hypertrophies are due to: 1, increased resistance in the vascular system, as in arterio-sclerosis; 2, to diseases of the heart muscle from infection, degeneration, etc.; 3, affections of the nervous system. The valvular disease usually has a previous cause. There may be a hypertrophy from natural causes. There may be a development of the heart walls with backward development of the thorax as pointed out by Germain Sée. There may be the hypertrophy of age, of work, of plethora, of pregnancy and of alcohol. In pregnancy there is increased work thrown on the heart due to an increased size of the uterus and mammae. In Munich, heart atrophy from alcohol is put down as third in the causes of death in that city. Syphilis, of itself, rarely affects the heart but the resulting arterio-sclerosis does. Bright's disease, as is well known, causes heart enlargement. Lead poisoning is another cause. Saturnism is more frequent than is usually supposed. Most cases succumb to heart failure and the real cause is not found out. Then other causes are diseases and deformities of the chest, em-

physema, kyphosis, myocarditis, gout, diabetes, irritation of the vagus, use of tobacco and excess of venery, mental troubles, success or failure in business. Look for the cause and treat it. Women are rarely affected in this way.

DR. J. P. CROZER GRIFFITH of Philadelphia, read a paper entitled "The Transmission of the Mitral Diastolic Murmur," the object of which was to call attention to the fact that these murmurs are often heard outside of the area usually given. He had seen several cases in which this murmur was heard up toward the axilla and even in the back.

DR. JAMES TYSON of Philadelphia, had seen one of the cases mentioned and had observed this fact in other patients.

DR. JAMES T. WHITTAKER of Cincinnati, said it was not so much to determine the position and extent of the murmur but to find the point of greatest intensity. The intensity of the murmur is indicative of the gravity of the disease.

DR. CHARLES CARY of Buffalo, spoke of the causes of these sounds and from the anatomic relations he thought that a regurgitation must often accompany these presystolic murmurs.

DR. JOHN H. MUSSER of Philadelphia, had been familiar with the work of Dr. Griffith and he related a case of his own. In referring to Dr. Whittaker's paper he had had mitral hypertrophy of the heart in which a mitral regurgitation relieved the headache, high tension and other unpleasant symptoms.

DR. MCPHERON of Montreal, thought that in these cases the loudness of the murmur depended on the tension of blood in the pulmonary circulation.

DR. A. H. SMITH of New York, said that a murmur that was diastolic may also in part be systolic when the mitral curtains were stiffened and did not coapt. There is a regurgitation which ceases when the pressure behind the valves reaches a certain point. It may be that even in health there is a little regurgitation.

DR. CHARLES G. STOCKTON asked if it was a diastolic or presystolic sound.

DR. GRIFFITH said in conclusion that the position of intensity is the position of mitral stenosis with no murmur over the aortic area and none over the sternum. As to the varieties and cause of the loudness he did not know, or whether an explanation had been given. Many things can not be explained as to the loudness of the murmurs. These murmurs were all pure murmurs. There is no difficulty in finding the diastole and systole.

DR. A. H. SMITH of New York, then read a paper on "The Use of the Differential Stethoscope in the Study of Cardiac Murmurs." With good hearing the differential stethoscope was very important in distinguishing between synchronous and alternate heart sounds in different parts of the chest.

DR. WHITTAKER said this was very well when the hearing was equally good in both ears which was so often not the case, but he thought the question of the position of the murmurs was not as important as the condition of the heart muscle.

DR. CHARLES CARY of Buffalo, read a paper on "The Cause of the Exaggeration of Sounds over the Right Upper Chest, both in Health and Disease," in which he demonstrated some specimens to show that there was an anatomic reason for this difference and showed the points of resemblance and difference between the two sides of the chest. Drs. Cary, Griffith and Tyson discussed this paper.

DR. CHARLES G. STOCKTON of Buffalo, reported "Two Cases of Fat Necrosis."

#### SECOND DAY, FRIDAY, MAY 31.

DR. WILLIAM H. WELCH opened the discussion on antitoxin. The decision of the good of antitoxin is in the hands of the clinicians and not of the bacteriologists. One observer says the question does not rest experimentally on a scientific basis. It is to be conceded that the Klebs-Löffler bacillus is the cause of diphtheria. These arguments would also hold against other diseases. The results of experiments are the most striking, but we have more in the application of the tetanus antitoxin. The introduction of its application to human beings is so that one can not argue from animals to human beings. The tetanus antitoxin is not efficacious because the poison or toxin of tetanus is cumulative and the antitoxin has no effect because it is too late. We do not know how the antitoxin acts, but that is no argument against its therapeutic action. This is also true of other diseases and this should not prevent us from using it. There are two prominent theories, the chemic and the vital theory. The antitoxin quite neutralizes the toxin according to the chemic theory, but the vital theory argues that the antitoxin acts through the changes of the serum on the cells to make them

immune. The vital theory seems to satisfy some demands. This method of treatment does not prevent post-diphtheritic paralysis. This complication is as common if not as severe after as before the treatment. These paralyzes depend upon the strength of the toxin. This is against the chemic and for the vital theory. There seems to be a quantitative relation between the toxin and the antitoxin, but there are no means of knowing how much toxin is in the blood and how much antitoxin to give and we may give too little. It is not known whether it exerts a direct specific action on the membrane or not. The benefits of the treatment are very doubtful when the antitoxin is introduced after the third day. Behring showed this in experiments on animals. We are not to expect brilliant results until we decide on what cases are diphtheria and what are not. As the organism is found in healthy throats this would include cases that were not recognized before and many cases which were not distinguished before, clinically, are now called diphtheria. On the other hand, there are certain cases of pseudo-membranous inflammation which are like diphtheria but which are not due to the Klebs-Löffler bacillus. If all these cases are taken into account the statistics of this disease will be markedly affected. As regards the proportion of cases like diphtheria but which are not, statistics differ, but my impression is that the very large amount of statistics from boards of health and hospitals give a wrong idea on this subject. It is not easy to find the bacillus and these examinations are usually made in a routine way, hurriedly, by inexperienced men and when we consider the difficulty of finding the organism we may say that in 30 to 40 per cent., it is not diphtheria and it is probable that not more than 5 or 10 per cent. of the cases are discovered. Then there are many complications of other organisms present which increase the difficulty. The mechanical obstructions in the larynx are to be taken into consideration. As to the direct effects of the antitoxin they are not different from those that may occur in the natural cure of the disease. Indeed the treatment is a natural cure; it is only a hastening of the natural cure. The statistical results are at the present time very elaborate, and from all sides and in all countries the figures would prove that this treatment is of great benefit.

From these statistics, various inferences may be drawn. They may include a large number of light cases and some mild cases may be called diphtheria when they are not. The agitation in the public press causes persons to seek treatment earlier than usual. Some say that of late the epidemics of diphtheria have been milder than formerly and cases would have recovered under any form of treatment. In some cases the antitoxin has no effect at all, possibly because the cells of the body fail to respond to the action of the serum. Then the general impressions of such men as Baginsky, Widerhofer and others obtained at the bedside are of value, and they are inclined toward believing in antitoxin. Kassowitz of Vienna, believes that this treatment has done much harm and says he has found at many autopsies evidences of the damage done to the body by this serum. Antitoxin is said to have no effect on the post-diphtheritic paralyzes and to cause more albuminuria, but it has certainly caused a more careful examination of the urine to be made in these cases. It is made out that albuminuria is found in from 83 to 76 per cent. of all cases treated. All arguments on the injurious effects of the serum should be based on whether it is given subcutaneously or intravenously. Skin eruptions and affections, chills, pustules, etc., are occasional injurious effects of the serum, but they are not permanent and they do not outweigh the benefits. There is certainly a reduction of the mortality from one-third to one-half, if the case is treated before the third day. The injurious effects of the remedy in some cases are certainly great, but the benefits far outweigh the harm done and the bad effects are usually only temporary. It will be a long time before final judgment can be given on this remedy.

Dr. MASON of Boston, reported a large number of cases treated at the Boston City Hospital, and the mortality and morbidity had certainly decreased. There may be some sources of fallacy; for instance there are more school inspectors and each child is carefully examined, and if the bacillus is found in its throat it is kept at home and the case is put down as one of diphtheria. The general appearance of a diphtheria ward now is different and the nurses and attendants are not afraid of such cases as formerly. Immunization is short, however. Some cases develop in spite of the injection. The effect of this treatment is more marked after the membrane is lost. In hospital there are few light cases, as they are rarely seen before the third day.

Dr. A. JACOBI of New York, is favorably inclined to this

mode of treatment, but the numbers as yet treated are far too small from which to draw conclusions. We do not want hundreds but thousands of cases. There have been seasons when the ordinary treatment with the bichlorid has been just as successful as the antitoxin is at present. He knew of forty cases collected some years ago and thirty-nine got well with the old treatment. Some persons refused the antitoxin treatment and preferred the old methods. When he used antitoxin he used other things too. It may not have been a scientific way but he wished to save his patient. Albuminuria is a very common symptom in any case, but he thinks he has had fewer cases since he has used antitoxin than before. He thinks the nephritis are less well marked. He related the effects of the treatment in his experience on the membrane, and spoke of the operations of intubation and tracheotomy and their frequency since antitoxin was introduced. He wished to place himself on record as a heretic. He thought the clinicians were too much in the hands of the bacteriologists. Diphtheria was not always caused by the Klebs-Löffler bacillus alone; the other organisms were also found in the membrane and he thought the clinicians accepted too blindly the statements of the bacteriologists.

Dr. JOHN S. BILLINGS thought that statistics to be of any value should be carried over a long period of time, and that in this question the value of hygienic principles should not be forgotten.

Dr. MASON said the only fair way to compare was by seasons.

Dr. A. C. ABBOTT of Philadelphia, wished to answer Dr. Jacobi. He thought the clinicians looked to the bacteriologists with good purpose, and the etiology of disease was in a very chaotic and tangled state until the bacteriologists lent a helping hand.

Dr. GEORGE M. STERNBERG said that the failure of tuberculin had brought such treatment into opprobrium and many were skeptical because the experiments with tuberculin on animals had not been successful.

Dr. F. H. WILLIAMS of Boston, showed a syringe that could be sterilized by boiling. It was made of glass with asbestos packing and to prevent the needle from breaking off, in the case of restless children, he put in a small piece of rubber tubing between the syringe and the needle.

Dr. WILLIAM OSLER reported a number of cases treated with antitoxin and four of them showed no Klebs-Löffler bacillus.

Dr. D. W. PRENTISS of Washington, then exhibited a patient, whom he had shown six years before with purpura hemorrhagica rheumatica. The boy had almost lost his sight but still worked. He had had good results with him by the use of phosphorus internally.

Dr. WILLIAM OSLER said, that Henoch had described this disease very thoroughly. 1, there are recurrences; 2, there are marked gastro-intestinal crises which may occur without any other manifestations; 3, the symptoms may be articular; 4, there may be hemorrhages under the skin, erythema multiforme, simple edema, hemorrhages from all the mucous surfaces and with all this an acute nephritis in many cases. There is little literature on the subject in English and the best work is Henoch's Festschrift. Drs. Stockton and Prentiss also discussed this paper.

Dr. J. G. ADAMI of Montreal, then reported a "Case of Madura Foot" (Mycetoma Pedis) which was probably the first case reported in this country. The microscopic appearance of the lesions reminds one of actinomycosis.

Dr. W. P. NORTHRUP of New York, read a paper on "Gonorrheal Arthritis," in which he reported several cases showing the joint affected, the swelling, exquisite sensitiveness, little fever, short course of four weeks, and recovery with perfect joint and the effusion was only serous.

Dr. WILLIAM H. WELCH of Baltimore, said that there was often absence of pus in the joints, and Dr. Halsted had found hemorrhagic effusion in many joints which he had examined. Dr. Flexner had accidentally found that an extract of fetuses of pigs made an excellent culture medium for the gonococcus. He also showed a specimen of gonorrheal endocarditis and from the patient Dr. Flexner had extracted some blood, mixed it with agar and obtained a culture of the gonococcus.

Dr. F. C. SHATTUCK of Boston, was surprised to find on looking up the literature how often two or more joints were affected. This paper was further discussed by Drs. Cary of Buffalo, Mason of Boston, Griffith of Philadelphia, Adami of Montreal, Roosevelt of New York, Osler of Baltimore and Northrup of New York.

Dr. A. JACOBI of New York, reported a "Case of Hyperthermia up to 65 Degrees C. (148 Degrees F.)." The man had fallen on deck and received an injury. The temperature

broke several special thermometers. He ran away from hospital finally.

DR. WILLIAM H. WELCH referred to a case reported by Dr. Galbraith of Omaha, where the temperature went up to 171 degrees F.

DR. J. GUITERAS of Philadelphia, made some observations on the "Spleen and Marrow in Leukemia."

DR. F. H. WILLIAMS of Boston, exhibited a "Comfortable Way of using Cold in Fevers."

DR. GEORGE DOCK of Ann Arbor, read a paper on "Goitre in Michigan."

DR. J. E. GRAHAM read a paper entitled "Displacements of the Liver."

DR. M. H. FUSSELL of Philadelphia, read a paper on "Carcinoma of the Liver with Cirrhosis."

DR. S. C. BUSEY of Washington, D. C., in collaboration with Dr. George M. Kober read a paper entitled "Milk as a Morbific and Infective Agent," with Tables of 134 Epidemics of Typhoid Fever, 73 of Scarlet Fever and 27 of Diphtheria due to Milk Infection.

DR. W. P. NORTHAUP of New York, exhibited the Fell-O'Dwyer Apparatus for Forcible Artificial Respiration.

DR. S. J. MELTZER of New York, read a paper on the "Direct Faradization of the Stomach and the Intestines in Animals, as Cats, Dogs and Rabbits."

### Illinois State Medical Society.

*Abstract of the Proceedings of the Forty-fifth Annual Meeting held at Springfield, May 21, 22, 23, 1895.*

[Special correspondence of the JOURNAL.]

(Concluded from page 896.)

DR. H. McKENNAN, of Paris, read a paper entitled

#### REPORT OF A CASE OF FOREIGN BODY OF THE TONGUE.

The author said it was for the purpose of showing the extreme tolerance to retain foreign bodies, of an organ much in use, that he presented a report of the following case which occurred in the practice of a neighboring physician, and through whose courtesy he was permitted to present the facts as stated below:

Otto G., aged 14, Jan. 18, 1895, while shooting an old rusty shotgun, burst the barrel and produced the following injuries, which were described by his physician, who saw him several hours after the accident as follows: "Face considerably burned by the powder, cut through the left side of the lower lip, about three-quarters of an inch in length; three of the upper teeth and a large piece of the inner surface of the alveolar process were gone; a smooth clean-looking wound of the tongue about the size of a silver 10-cent piece was found a little to the left of the apex, with no evidences of a foreign substance present. The whole organ was swollen, and the boy was unable to talk. The parents opposed the use of an anesthetic. The doctor cleansed and dressed the wound as perfectly as the nervous condition of the patient would permit. On the following day the salivary glands were stimulated to great activity, and a profuse flow of saliva continued through the day. Patient could not articulate sufficiently to be understood, and was totally unable to swallow. He was fed by means of a stomach tube, and on the third day was able to swallow liquids sparingly. The patient improved gradually and in the course of a few days all the wounds were healed, and at the end of a month he returned to his home in the country, where he was able to attend to his usual farm duties. He claims to have suffered no pain or inconvenience except that his tongue seemed heavier than it had ever been before. He was able to talk as well as usual. One day, while at work on the farm, he noticed the click of a metal substance against his teeth. He immediately presented himself to his physician, who was greatly surprised to find protruding from the former wound of the tongue, the screw-end of the breech-pin of the old shotgun. This foreign body remained imbedded in the tongue fifty-four days, and measured one and a half inches in length, three-quarters of an inch in breadth, one-half inch in thickness and weighed three-quarters of an ounce. Owing to the protected position of the tongue in the body, injuries to this organ from external violence are comparatively rare. When injuries do occur they are usually in the nature of shotgun or penetrating wounds.

In Dennis' "System of Surgery," vol. I, Professor Conner, speaking of wounds of the tongue, on page 488, says: "In passing through the mouth a bullet often wounds the tongue, either grooving it or tunneling it. In rare instances the ball lodges, and cases are on record in which it has remained in place for years."

Dr. McKennan regarded this case as unique, and believes it is without a parallel on record.

DR. ARTHUR D. BEVAN, of Chicago, read a paper on "Mas-toid Disease and Resulting Venous Thrombosis and Brain Abscess."

DR. A. C. CORA, of Carlinville, followed with a paper entitled

#### TRACHOMA OF THE CONJUNCTIVA, FOLLICULOSIS OF THE CONJUNCTIVA, GRANULATED LIDS, NOT A DISEASE OF ITSELF AND OF ITS OWN KIND.

The author quoted various authorities on diseases of the eye, pointing out what is in the main regarded as the cause, origin and nature of this disease, and said that for some years he had spent much time in looking for an assemblage of symptoms that would enable him to readily recognize this disease, and at this date he is forced to the conclusion that entitles this paper. Within the past few months there has come to his hands what seems to him an indisputable demonstration that folliculosis and trachoma of the conjunctiva is a condition arising out of, and because of, continued irritation or inflammation of the conjunctiva of various kinds, and *not itself* depending on a microbe or specific infection. Dr. Corr then referred to a paper read before the Wisconsin State Medical Society, June 6, 1894, by Dr. H. V. Würdemann, of Milwaukee, and published in the *Ophthalmic Record*, October, 1894, entitled "Pathology of Granular Conjunctivitis."

Dr. Corr said that the author of this paper had elucidated the subject more perfectly than it would be possible for him to do, and that therefore he would content himself with quoting the salient points, which he did.

DR. J. HOMER COULTER, of Chicago, contributed a paper entitled

#### WHEN AND HOW TO OPERATE IN ANTRAL EMPYEMA.

The author said that this was one of the most mooted questions in rhinology to-day. It was not in the hope of having it thoroughly settled that he ventured to call the attention of the society, made up largely of general practitioners, to the subject, but rather that by a brief survey of the opinions of specialists and the reasonable deductions therefrom, he might be able to assist the practitioners in the earlier and more certain diagnosis of the condition. Many of these cases go a long time unrecognized, and thus become proportionally serious conditions. Reference was then made to the etiology of the disease, as well as to the symptomatology.

The objects to be obtained by any surgical procedure were: to form an exit for the pus; to destroy the pyogenic membrane; to establish as nearly as possible a normal functional activity of the cavity, and the surrounding mucous membrane. Dr. Coulter maintains that an operation should be done in the majority of these cases, considering: 1, the ease with which the operation can be done; 2, the good results to be expected from the operation when properly and thoroughly done; 3, that bad effects or misfortunes are unusually rare considering the severity and extent of the operation; 4, that, as elsewhere, the earlier the operation the better, when at least a reasonably certain diagnosis of empyema has been made; 5, an exploratory puncture in case of doubt is both harmless and confirmatory, hence advisable; 6, no one operation will suit best for every case.

As to the question of *how* to operate, the operation must necessarily be done: 1, in the canine fossa; 2, through the alveolus; 3, in the middle meatus; 4, in the inferior meatus; or 5, the Talbot-Fletcher operation. Various procedures were then described. The author favors the method of operating through the inferior meatus.

The operation which he terms the Talbot-Fletcher method is a thoroughly practical one, a minute description of which may be found in the JOURNAL for Nov. 24, 1894. It consists in boring a hole through the anterior wall of the antrum at the base of the malar process, midway between the root of the second bicuspid and the first molar tooth, directing the drill upward and backward, the antral wall being easily pierced.

DR. OSCAR J. PRICE, of Chicago, read a paper on

#### INFECTED WOUNDS.

The most common habitat for pyogenic organisms with which we have to contend, in the management of infected wounds, is found upon the skin in close relation to the wound; especially if the parts are naturally moist; and also from the fingers of the surgeon or his assistants; infected instruments which have not been properly sterilized; dust which may be charged with dry and floating germs; ordinary

poultices and common water dressings; unclean towels and tables; contact with ordinary clothing; dirt, grease and uncleanliness generally; exposed gauze and drainage employed which through inattention has lost all germicidal properties, and is thus frequently the nidus of auto-infections. These are the more common means not only of producing infected wounds, but often of re-infection after the original invasion has been controlled. But in the time allotted, the author said it was not possible to pursue the etiology of infection further than to outline some of its general principles. The author then proceeded to a consideration of the pathologic phenomena presented in the development and progress of infected wounds, detailing the symptoms of this class of wounds.

The treatment will depend in a great measure upon the location and condition of the part. In penetrating wounds of the abdomen involving the peritoneum, it is good surgery in most cases to enlarge the opening sufficiently to inspect the injured parts; to surgically correct damaged conditions so far as possible; to gently sponge away all recognizable elements of infection, but to avoid all irrigations with any strong antiseptic solutions, as being likely to spread and disseminate the elements of infection existing. The object is to cleanse locally and to secure the most satisfactory and thorough drainage commensurate with the amount of damage done. The management of penetrating wounds of the thoracic cavity must depend to a great extent upon the evidences of infection presented. If there be a protrusion of the lung in an infected condition, or if portions of clothing or other foreign matter have been carried in, we are undoubtedly justified in enlarging the opening that such foreign matter may be removed, and the surrounding parts carefully cleansed and as thoroughly disinfected as possible, and providing, here as elsewhere, thorough drainage for the suppuration which is so likely to occur by the introduction of drainage tubes covered by a piece of protective, forming a valve to the opening, to prevent the ingress of fresh air. If the cavity is considerable, there should be a counter opening made at the most dependent or lowest portion, in which is also placed a similar drainage tube. The author does not wish it to be understood that this mode of procedure should apply to all cases of penetrating wounds of the thoracic cavity. Bullet and incised wounds were then dwelt upon, as well as the treatment of compound fractures attended with much laceration and evidences of infection.

Dr. E. WYLLYS ANDREWS, of Chicago, followed with a paper entitled

#### THE LAP-JOINT, OR IMBRICATION METHOD FOR THE RADICAL CURE OF HERNIA.

At the outset, the author stated that this interlocking or overlapping principle is not limited to one application, but may be applied to other wounds of the abdominal wall in certain cases which he would not discuss at this time. As applied to curing hernia, it is not intended so much to supplant as to reinforce existing methods, one or two of which are a great advance over those of a few years past, and which Dr. Andrews briefly considered.

For descriptive purposes, he classed all radical cure operations upon inguinal hernia as of two distinct types, namely, the *first or early type*, and the *second or modern type*. These types were then dwelt upon at considerable length.

The author summarized his remarks with the following conclusions:

A successful method must be a true plastic operation upon the musculo-aponeurotic walls, especially the posterior wall and internal ring. Adhesive peritonitis in the sac walls and cicatricial tissue in the canal are of no permanent value in radical cure.

The advantages of imbrication are:

1. Large strong flap to repair posterior wall.
2. Triplicate layers of aponeuroses increasing strength.
3. Broad surfaces instead of free edges, securing better union.
4. Shortening of anterior wall gives support to the deeper sutures.
5. Cord is amply protected.

Dr. EDMUND ANDREWS, of Chicago, read a paper on SOME OF THE EVILS CAUSED BY WHITEHEAD'S OPERATION FOR PILES, AND BY ITS MODIFICATION, THE SO-CALLED "AMERICAN OPERATION."

Whitehead's operation for piles has been in use about ten years. It was devised by Mr. Whitehead, of Manchester, Eng., and consists in dissecting out the whole lower inch of the mucous membrane of the rectum, and with it all the piles and hemorrhoidal vessels, and most of the submu-

cous connective tissue, leaving the internal sphincter muscle pretty nearly stripped naked. The first incision is a circular one, following the junction of the mucous membrane with the skin, called Hilton's white line, and dissecting up between the veins and the sphincter. Dr. Andrews then exhibited a cut representing the operation at this stage.

He said that certain persons calling themselves "official" surgeons, had slightly modified the order of procedure by pulling down the mucous membrane and making the upper circular incision first, and the lower last. They had given the procedure with this trivial alteration the pompous title of the "American operation." A surgeon in Berlin made the same change, but he did not call it the German operation. The principle is the same, namely, the complete removal of the mucous membrane, veins, and most of the connective tissue from the pile-bearing inch of the bowel, the motive being to prevent the possibility of any more piles on that area.

Those who favor Whitehead's method say that it should be used wherever the whole circumference is occupied by the dilated veins. Some eminent authors seem totally ignorant that a cure can be accomplished with ease and certainty by either the ligature or by the clamp and cautery in all those cases. It is never necessary to directly include all the dilated veins in the operation. If about half the height of each pile is destroyed, the intervening varicosities shrink away and disappear.

Dr. Andrews had corresponded with some of the most eminent surgeons both in Europe and in this country regarding Whitehead's operation, and after his rather extensive investigations in this regard, he is on the whole discouraged about Whitehead's method ever becoming a safe and desirable operation. If, however, any one thinks otherwise, and desires to continue its use, he suggests the following precautions: bear in mind that it is never necessary to completely dissect out all the enlarged veins. If considerable portions are removed, the remainder always shrink away; therefore, make the lower incision somewhat above Hilton's white line, even if there are external piles temporarily left below it, and in like manner make the upper incision low down, cutting off the cuff somewhat below the top of the internal piles, thus saving as much of the tactile mechanism of the lower rectum as possible, for the special sense located in this tract is of great importance to the patient's future comfort. Finally, the surgeon should remember the peculiar difficulty of the antisepsis and be diligent accordingly in attempting it.

Dr. CHRISTIAN FENGER, of Chicago, made some extemporaneous remarks on plastic operations on the hand to remedy deformities caused by injuries and burns, and exhibited a patient upon whose hand he had performed a successful plastic operation.

Dr. J. A. BAUGHMAN, of Neoga, followed with a paper entitled

#### A CASE OF UMBILICAL HERNIO-LAPAROTOMY, AND AN ENTERECTOMY.

In the first case, a patient 40 years of age, weight 235 pounds had for four years suffered from a painful umbilical hernia of about the size of an orange. The operation was done in the usual manner. Four and a half months after the operation, she returned with a knot the size of a hazel nut, detectable but not visible near the seat of the operation. The author cut down upon it and found it to be an epiploic-phalocele.

The second case was an enterectomy in which eighteen inches of the small intestine were excised.

#### A PLEA FOR MODERN CÆSAREAN SECTION.

This paper was read by Dr. C. P. HARRIGAN, of Chicago. The author prefaced his remarks by saying that craniotomy upon the living fetus is in direct violation of all accepted principles of modern surgery; that it is an irrational unscientific procedure from any standpoint. The author made a strong plea for Cæsaean section, fortifying his position by numerous quotations from leading surgeons. For instance, Professor Lusk said he had had five cases of Cæsaean section; three recovered, and two died. The latter were both kyphotic dwarfs. The operations were not especially difficult. Death occurred at the end of a week from feeble vitality due to undeveloped lungs and heart. In one case, the former weighed but eleven ounces, the latter about five ounces. The mortality in kyphotic patients has been unduly great. Dr. Joseph Price says, "that craniotomy should only be performed upon dead children and monstrosities. Upon healthy children it should never be resorted to." Price urges Porro's operation for prophylactic reasons.

## SECTION III.

## Section on Etiology, State Medicine and Medical Jurisprudence.

Chairman, DR. SANGER BROWN, Chicago.

Secretary, DR. WILLIAM BARNES, Decatur.

The address of this Section was delivered by DR. JOSEPH J. KINYOUN, U. S. Marine-Hospital Service, Washington, D. C. DR. KINYOUN selected for his subject

## THE MANAGEMENT AND CONTROL OF INFECTIOUS DISEASES IN MUNICIPALITIES.

His object was not to enter into a discussion of all the details incident to the control and management of disease in municipalities, but to confine his remarks to a consideration of a class of diseases known as infectious or contagions.

Cholera was dwelt upon at considerable length. Some of the acutely epidemic diseases had in the past been indirectly conducive of great good to our present civilization. Cholera had pointed out the danger from polluted water, and had been largely responsible for a pure or better water supply for our cities. By way of contrast, typhoid fever and tuberculosis were cited as examples. If we compare the mortality of one of these with that of cholera, the difference is strikingly in favor of cholera.

A few cases of yellow fever in one of our Northern cities would not, in the present state of our knowledge, be a menace. It can be easily managed. Disinfection of the infected apartments and their contents will be all that is required.

Typhus fever, while resembling in many respects yellow fever, differs materially in the manner of its spread. It is a house disease, and is due to unsanitary conditions for its propagation. It is far easier to handle than yellow fever.

Smallpox appears even at the present time to be the *bête noir* of our civilization. There is no necessity for the existence of this disease, said the author, at the present time, if the least common sense were exercised in regard to it. We know of the beneficent effects of vaccination and revaccination, and still we have plenty of it in our midst.

From experiments made by the author he was of opinion that the great mortality from smallpox would be reduced by serum therapy.

Tuberculosis was next considered, the author saying that there was no city, village or hamlet which escaped its ravages. Tuberculosis, as now understood, is an infectious disease, its specific agent being a bacterium which is thrown off in the discharges of those affected with it. It is highly communicable from one person to another.

Typhoid fever may or may not be considered epidemically an infectious disease. It depends entirely upon the channels of infection and the conditions of environment. If the disease is contracted through a water supply, be it a well, or from a general supply, the importance of its recognition is unquestioned.

Diphtheria. Nearly every municipality which has seen fit to promulgate regulations for the control of infectious diseases has given prominence to the control of diphtheria. It is preëminently a disease of communal life. The fact of its attacking the young makes it more to be dreaded as a school disease. The author then dwelt upon the methods of making cultures in cases of suspected diphtheria, and considered the following subjects *seriatim*—notification, disinfection, house disinfection, preventive disinfection, and ambulance.

DR. N. S. DAVIS, of Chicago, read a paper entitled

## THE PRESENT STATUS OF BACTERIOLOGIC INVESTIGATIONS AND THEIR RELATIONS TO ETIOLOGY AND THERAPEUTICS.

The two leading facts which Dr. Davis desired to emphasize in his paper are: 1, the constant tendency on the part of the profession to draw hasty conclusions from incomplete investigations; and, 2, the failure to hold fast what appears well established in the past until the actual bearing of new facts or discoveries can be fully ascertained. In no other field of investigation is there so much caution and patience required as in that of therapeutics or the direct application of remedies in the treatment of disease. And there are certain well-established facts that must be constantly kept in mind by every investigator if he would avoid error:

1. It must be remembered that all acute, zymotic and epidemic diseases are self-limited in duration. That is, they are either cured or kill the patient within a limited period of time. Each case has its initial stage of development, of active progress, culmination and decline; because the physiologic processes of every living body tend to either destroy or eliminate every disturbing agent that has found entrance into it. Therefore, the first step in all reliable therapeutic

study is to know the natural tendency of the disease we propose to treat, the average duration of each stage and, if possible, the natural processes or channels through which the offending cause is destroyed or eliminated. Without such knowledge of the disease, all exhibition of new remedies is only blind chance experimentation, and as likely to hinder or embarrass the natural processes as to facilitate their beneficial work.

2. In comparing the success or beneficial effects of one remedy with another, it must be remembered that all acute diseases vary in their severity and fatality in different years, in different localities the same year, and in different individuals in the same locality. Also, that all epidemics are less fatal during the period of their decline than at the period of invasion. Consequently, the real value of no treatment can be determined until it has been tested by many persons, at different periods of prevalence of the disease, and at different stages of epidemic progress.

3. It is necessary to know the nature and actual *modus operandi* of the remedy we propose to use.

Finally, when a microorganism, ptomaine, or toxin is found in connection with any disease, the first question to determine is, Does it stand in the relation of a cause or an effect of the morbid processes constituting the disease? These are fundamental propositions, without observance of which we are constantly led into erroneous conclusions and contradictory results.

DR. GEORGE H. WEAVER, of Chicago, read a paper on

## THE BACTERIOLOGIC DIAGNOSIS OF DIPHTHERIA; THE NEED OF ITS GENERAL USE AND ITS TECHNIQUE.

The author emphasized the importance of a bacteriologic examination of all cases of sore throat in which there is any pseudo-membranous formation, and of every sore throat, even if no such formation is present, in case children are liable to exposure.

The most important reasons for having a correct diagnosis may be stated as follows:

1. The treatment of the individual case would be modified by it. The diphtheria antitoxin is useful in only such cases as are caused by the diphtheria bacillus, and as it is not certain that it is absolutely harmless, it should, for the present at least, be used only after a positive diagnosis, except in very urgent cases.

2. The finding of the diphtheria bacillus would necessitate an absolute isolation of the patient, however mild the attack, until virulent bacilli were no longer present. The virulent bacilli persist in the throat and nasal cavities after apparent recovery and disappearance of the pseudo-membrane, for weeks at times, and the only way to rationally limit the period of isolation is to insist upon its continuance until all possible danger of contagion is past—until virulent bacilli are absent. If diphtheria bacilli are not found, there is little or no danger of contagion, and isolation is not demanded.

3. The disinfection which should follow in cases of true diphtheria, is thorough and complete, while in the case of false diphtheria it is unnecessary.

4. In the absence of a positive diagnosis by bacteriologic methods, at least every case of sore throat showing any pseudo-membrane should only be consistently managed by treating it as a case of diphtheria.

Dr. Weaver then discussed the questions of how the methods required may be adapted to various conditions of population, and the technique to be employed in each case.

DR. D. D. BISHOP, of Chicago, read a paper entitled

## GENERAL MICROSCOPIC EXAMINATION OF THE BLOOD.

When making an examination of blood in hospital practice where one has the apparatus necessary for a complete study, the author says the following observations should always be made:

1. A count of the number of red and white corpuscles per cubic millimeter.

2. An estimation of the percentage of hemoglobin present.

3. A cover-slip preparation of fresh blood is examined concerning the following possible conditions: (a), apparent changes in the color of the red blood corpuscles; (b), changes in the size of the red blood corpuscles, noting whether there be present corpuscles much smaller than normal, microcytes, or those larger than normal, macrocytes; (c), changes in the form of the red corpuscles, poikilocytes; (d), the presence or absence of Laveran's organisms of malaria; (e), a number of spread cover-slips are then taken and preserved for subsequent examination by the color test, as recommended by Ehrlich.

The Thoma-Zeiss blood counting apparatus is used in esti-

inating the corpuscles. The hemoglobin estimate is performed by means of Von Fleisch's hemometer.

Though much has been done by Schultz, Bizzozero, Hayem, Osler and others, in the histology and pathology of the blood, by the study of fresh specimens, it was left to Ehrlich to introduce in 1878 the method of staining cover-slip preparations, which Dr. Bishop then described.

Dr. J. L. WIGGINS, of East St. Louis, followed with a paper entitled

INFLUENCE, RESPONSIBILITY AND PROFESSIONAL DUTY OF THE  
PHYSICIAN IN MATTERS OF PUBLIC HYGIENE AS RELATED  
TO MUNICIPAL GOVERNMENT.

Sanitary science broadens out and fills one with wonder as he contemplates the vastness of its application. It is difficult for us to say just when to leave off and in what manner to enforce rules to the end that the community can be protected, and still retain the rights of the individual. Shall the State undertake to say when and where we must bathe? What we must eat or drink? The kind and texture of our clothes? Hardly, yet the State has certain duties, and to the degree in which these are observed will she prosper. The first and most necessary condition is in the selection of a capable and educated sanitary officer. Each community of 10,000 should have a health officer or an assistant. By this means the average of life would be raised and death and sickness reduced to a minimum.

Dr. A. C. CORR, of Carlinville, read a paper entitled

EMASCULATION AND OVARIOTOMY AS A PENALTY FOR CRIME IN  
THE REFORMATION OF CRIMINALS.

This paper formed the basis of a symposium of contributions which were read at the last annual meeting of the Society, and the various propositions contained in them were taken up and discussed *seriatim*. Dr. Corr said that the criminal defect is often a mental complex, a bi-product of apparently normal mental conditions of ancestors, neither of which were criminally inclined. To have been inherited, it must be a like trait to that which was exhibited in the ancestors, one or the other. He is acquainted with the Harry Hayward family on both sides, but they were not criminals. He is also acquainted with a Methodist minister who had been a presiding elder; he and his wife are amiable people, and above reproach, yet their two sons are both criminals. Some families are all criminal but one, and where is the flock without a black sheep?

The following officers were elected:

President, Dr. D. W. Graham, Chicago.

First Vice-President, Dr. J. M. G. Carter, Waukegan.

Second Vice-President, Dr. T. J. Pitner, Jacksonville.

Permanent Secretary, Dr. John B. Hamilton, Chicago.

Assistant Secretary, Dr. J. R. Hoffman, Ottawa.

Treasurer, Dr. George N. Kreider, Springfield.

Members of Judicial Council, Drs. J. F. Percy, of Galesburg; J. O. DeCoursey, St. Libory, and Carl E. Black, Jacksonville.

Chairman of Section I, Dr. J. F. McAnally, Carbondale; Secretary, Dr. C. W. Hall, Kewanee.

Chairman of Section II, Dr. J. H. Coulter, Chicago; Secretary, Dr. L. C. Taylor, Springfield.

Chairman of Section III, Dr. H. N. Moyer, Chicago; Secretary, Dr. W. R. McKenzie, Chester.

Next place of meeting, Ottawa, third Tuesday in May, 1896.

Committee of Arrangements, Drs. J. W. Pettit, T. W. Burrows, E. H. Butterfield and E. W. Weis, of Ottawa.

Committee on Necrology and Biography, Drs. J. H. Hollister, Chicago; O. B. Will, Peoria, and E. J. Brown, Decatur.

Committee on Medical Legislation, Drs. C. C. Hunt, Dixon; B. M. Griffith, Springfield; J. B. Maxwell, Mt. Carmel, and the President, *ex officio*.

Committee on Medical Societies, Drs. E. J. Brown, Decatur; Jacob Schneck, Mt. Carmel, and W. S. McClanahan, Woodhull.

Medical Society of the State of Pennsylvania.

Proceedings of the Forty-fifth Annual Meeting held at Chambersburg, Pa., May 21, 1895.

[Special correspondence of the JOURNAL.]

(Continued from page 893.)

THE ADDRESS IN OBSTETRICS

was given by Dr. W. B. ULRICH of Chester. After alluding to the origin of this appointment he spoke of the value of the papers under this head which had been presented. He held to the opinion that labor is a purely physiologic function; there is no unnatural labor. He divided labor into ordi-

nary or uncomplicated, and exceptional or difficult labor. The first comprise nine-tenths of all, needing simply cleanliness and as little interference as may be. Normal may be converted into pathologic by too frequent examination. Laceration may be caused by the desire to hurry things. In the majority nature is competent, needing no assistance. The woman can not be compared to a case of amputation, with the expectation of blood poisoning, needing vigorous antiseptics to prevent it. Otherwise how could the human race have survived all these dangers? How about savage races, with their barbarous methods? He is also opposed to instrumental delivery to suit the convenience of the physician. We should learn when not to use the forceps. Traumatism may result and a dangerous train be fired. Consider only the patient. The duty of the obstetrician is cleanliness or asepsis. He believed with the old country doctor, who boasted that plenty of lard and a good deal of patience were all the instruments he wanted. He insisted upon the usefulness of a warm soap and water bath at the beginning and a douche to cleanse the birth canal, especially if the patient does not seem clean, yet was opposed to repeated douchings and irrigation of the uterus after labor, except where absolutely indicated to overcome an actual septic state, due to retained placenta, etc. Chemic disinfectants are not required and their routine use is to be deprecated. On the other hand, he commended the practice of rendering the hands of the obstetrician and all instruments used by him as aseptic as possible by the abundant use of soap and hot water. Follow this by a rinsing with solution of bichlorid 1 to 2000. Thus puerperal septicemia may be eliminated. By this plan Dr. Joseph Price claims that he has not had a case in nearly 10,000 labors. Again we may thus abolish ophthalmia neonatorum. Three-fourths of the blind asylums might be closed. He did not attempt to give a record of his cases, but in a practice of forty-six years his obstetric cases had run into thousands, yet he had never had a dozen sore eyes, and not a single infant had lost its sight. He had never lost a case in labor. He alluded to the law framed by a committee of this society to prevent blindness, making it incumbent upon midwives, etc., to see that an infant with sore eyes shall receive prompt attention that its sight may not be lost. He approved of this, but still considered prevention better. Absolute cleanliness in the conduct of labor is conducive to the best interests of both mother and child. He frowned on the fad of routine use of anesthetics in labor. Who can tell the effect of these pains, the result of Nature's force? Anesthetics, the hasty removal of the placenta are fruitful of post-partum hemorrhage, and of asphyxiated infants. Unless there is good reason, the ergot should remain in the bottle, as well as the castor oil, quinin and the malt liquors. Let well enough alone.

Meddlesome midwifery is bad; so is officious medicine giving. In case of eclampsia at term, and in placenta previa requiring rapid delivery he spoke highly of the method of rapid manual dilatation and delivery of Dr. P. A. Harris of Paterson, N. J., first described in the *American Journal of Obstetrics* last year. Dr. Harris reported his experience in placenta previa and eclampsia; that in all cases there were no labor pains or partial dilatation before he attempted delivery; he had not lost a single case. Since the introduction of asepsis, symphysiotomy has been revived and is largely practiced with increasing success. He quoted from the paper of Dr. Fox of last year and also from Dr. Harris of Philadelphia, who is now enthusiastic for this operation. He described the operation as performed by Professor Farabouef. The woman is placed in the dorsal position, thighs abducted, flexed on the abdomen, the pubic region shaved, this and the adjacent parts washed with soap and water, then with sulphuric acid, finally with bichlorid solution. The patient is fully anesthetized, catheterized and a vaginal douche given. The length of the incision varies with the length of the symphysis; it must be made vertically, midway between the two pubic spines, beginning at the level or a little above the superior border of the symphysis, descending to its inferior border, deviating in the region of the clitoris without touching superior part of the vulva. Then cut through all the soft parts down to the cartilage not stopping to seize vessels. Then upon the index acting as a guide, with the scissors divide the fibro-cartilage at the level of the anterior surface and superior border of the symphysis. Then we make two small incisions transversely, beginning at the median line close to the superior border of the symphysis in such a way as to cut through the aponeurotic tissues in order to make a passage for the index, which is then introduced along the posterior surface of symphysis. The finger then feels very well the posterior prominence of

the fibro-cartilage of the symphysis. Left in this position it serves as a protection to the organs lying posterior to the symphysis. With a straight scalpel, begin cutting the cartilage from before backward and from above downward, and finish the section by means of a blunt-pointed bistoury. At the moment of cutting the sub-public ligament, by means of a sound in the bladder the assistant pulls the urethra out of the way. The incisions through the cartilage are kept up as long as the knife continues to creak, for the latter indicates the resisting cartilage and ligaments giving way. Finally the iliac bones in a measure separate. The assistants now practice slow and progressive abduction of the thighs. The cartilages separate, one, then two fingers are introduced. Experience teaches no damage can be done to the articulations by a separation of 7 centimeters. When this is reached, the assistants are warned not to move and a tampon is placed in the wound, either of sponge, cotton or iodoform gauze. We now extract the fetus, apply the forceps and pull; the head descends, separating the pubis if not already sufficient. Do not exercise too much force. Let the head rotate. Now Dr. Varnier, in order to protect the vulva, etc., has the assistants approximate the thighs causing the iliacs, etc., to resume the normal position, and the head is delivered without injury to the inferior osseous and muscular straits or vulvar orifice.

The operation is terminated; a vaginal injection is given, the placenta removed, the vagina packed with gauze and next the pubic wound is cared for. The tampon is removed, the wound irrigated with a 5 per cent. carbolic solution, the assistants approximate the iliacs by continued pressure on the hips and the operator sutures the tissues with two or three buried sutures, and as many as needed to keep the parts in apposition. The wound is covered with gauze and absorbent cotton. A tight bandage is placed around the pelvis, this covered with a second, in the form of a T. A third supports the parts and for this plaster-of-Paris is used. This is applied in an oblique position to leave the pubic region free and for future dressings and these must be removed as soiled, at least twice a day, for they are always soiled at micturition. The vaginal dressings may be allowed to remain two or three days as it insures antiseptis of the vagina, and we can dispense with the injections otherwise needed. The limbs must be immobilized by strapping. About the eighth day the wound has cicatrized. Often the edema has caused the sutures to cut through. These may be taken out at the rate of one or two a day.

This operation saves the child, with a minimum of danger to the mother. It is far preferable to the Cæsarean operation or craniotomy.

In concluding, he alluded to labor delayed by unusual positions. He had not found it an easy task to change a malposition. With the present asepsis, we should more commonly resort to the effort to change vertex posterior into anterior. For many other treatments, in complicated labor, special training and sound judgment are needed. In conclusion, he made a plea for careful diagnosis, and not too much zeal for manual and mechanical interference.

Dr. T. J. MAYS, of Philadelphia, read a paper on "Fat in Pulmonary Consumption." Fat is one of the most important constituents of the body. It always diminishes in pulmonary consumption. It is a special secretion and is manufactured out of carbohydrates, proteids and fats, but for fattening purposes proteids and carbohydrates are superior to fats and oils, and therefore the latter are over-rated in the treatment of consumption, although valuable adjuvants. It is also shown that resting the invalid promotes the formation of fat, while exercise retards it; that in all probability the production of fat is under the control of the nervous system and that strychnin through its stimulating influence on the nervous system fattens the consumptive and increases the number of his white and red blood corpuscles. He gave short abstracts of the histories of fourteen patients, who were treated in accordance with the principle advocated here, which show a total increase of 350 pounds, or an average gain of nearly 22 pounds.

"Ligation of Arteries in Malignant Disease," was read by Dr. JOHN H. PACKARD, of Philadelphia. He spoke of the limitations of surgical treatment of malignant disease, of the conditions causing suffering and demanding relief, then of the dangers; finally he detailed the conditions under which the ligation of arteries may be available to afford relief, or facilitate further treatment. He concluded by quoting cases which appeared to uphold his method by the good results obtained.

Dr. JANE K. GARYER, of Harrisburg, read a paper on "Heredit," which was an effort to show something of heredity

and its power in the causation of insanity; something of the increase of the same as shown by statistics, with her view of the reasons for that increase, as well as the desirability of inaugurating new methods in the prevention of insanity.

Dr. H. G. McCORMICK, of Williamsport, presented a paper on "Management of Cases of Typhoid Fever." He had employed guaiacol with most excellent results.

"Labor complicated with Typhoid Fever," was the title of a paper by Dr. W. M. FINDLEY, of Altoona. Case was taken ill three months prior to accouchment with the usual symptoms of high range of temperature, etc. As there were three other cases in the house, the case was an undoubted one. Progress of disease was normal but severe. In due time labor set in at full term, second birth, vertex position. The bowels became much relaxed, evacuations frequent, and copious. By the liberal use of stimulants and application of the forceps, labor was terminated in four hours; child alive. Mother made a good recovery; child was minus the epidermis as though parboiled, but is living at the age of 21 years, though not strong.

Dr. T. DYLLER, of Pittsburg, read a paper on the "Influence of the Mind in the Treatment of Disease."

On motion of Dr. J. ROEBUCK, of Lititz, it was resolved to send delegates each year to the Pennsylvania Pharmaceutical Society.

On motion of Dr. S. SOLIS-COHEN, the exhibition of drugs was to be restricted to the pharmaceutical preparations known as to their ingredients, etc.

In the evening the session was resumed at the Wilson College for Young Ladies. After some musical entertainments Dr. JOHN B. ROBERTS delivered the Presidential Address. His subject was

#### THE PRESENT ATTITUDE OF PHYSICIANS AND MODERN MEDICINE TOWARD HOMEOPATHY.

This address presented in a semi-popular manner the differences between modern or rational medicine, and homeopathy, quoting the definitions given by standard dictionaries.

Homeopathy, as advocated by Hahnemann, was described as a school of medicine, while non-sectarian medicine was designated as a science, since it is in no way founded upon a theory or hypothesis, but the result of investigation of chemico, physiologic and physical facts. The reasons were given which prevent the physicians who subscribe to no dogma from accepting the doctrines of Hahnemann. The statement was made that many physicians who are called homeopaths are not believers in all of Hahnemann's theories. Long quotations were made from Hahnemann's "Organon," and recent homeopathic writers. These quotations showed that there are still some homeopathic physicians who believe in the increase of drug power by diminishing the dose, and in the efficacy, as a means of treatment, of the so-called universal and infallible law of "similars." The attitude of physicians who accept no sectarian name was said to be a dual one. Some of them hold that homeopaths who do not believe in the universality of Hahnemann's law should make a public formal statement before being admitted to the right of consultation with members of the non-sectarian medical organizations. Others believe that the profession and the public would be benefited if a graduate of a homeopathic college or a member of a homeopathic society, who simply indicates his willingness to treat patients by all means, should be admitted to the rights of consultation.

The author did not indicate to which of these classes he belonged. The paper was not written in a controversial spirit, but seemed to indicate that the author desired to permit the hearer to draw his own conclusions as to the relative merits of the case.

The sessions were resumed at 9 A.M., Thursday.

Dr. F. X. DERCUM, of Philadelphia, delivered the

#### ADDRESS IN MENTAL DISEASES.

The peculiar position which insanity has occupied in the past, in the minds both of the laity and of medical men was first dwelt upon, and also the further fact was emphasized that the first attempts to provide for the insane were purely of a practical and utilitarian character and embraced little more than the isolation and housing of the insane. The present status of the pathology of insanity was then taken up. The speaker alluded to the researches of Golgi, Raymond y Cajal, and especially to the investigations of Lloyd Andriezen. It was pointed out that through these labors the structure of the normal cortex was at length being revealed and further that, as Andriezen had shown, we were now in a position to correlate symptoms with change of

structure, at least in certain forms of insanity, for example, alcoholism. In the latter disease there are not only evidences of gross and general nutritive changes in the cell bodies, but also alteration and destruction of the fine naked collaterals and nerve terminals of the molecular layers of the cortex. These changes explain the diminished sensitiveness of the alcoholic subject to impressions from without and also the general loss of memory and lack of association of ideas. Here was the first instance in the history of insanity in which it has been possible to correlate, closely, structural change and symptom. It was, however, pointed out that while such results are sufficient where the poison producing the changes is definitely known, microscopic examination can not give us all the information that we desire when the initial cause is not known. At most, it can only reveal to us the effects of pre-existing causes, and leaves us in the dark as regards the causes themselves. This fact led to the consideration of the subject from another aspect. The conviction is steadily growing in the medical mind that the actual agents which produce tissue changes are chemic toxic substances of one kind or another; some of them absorbed or ingested from without, others the poisons produced by altered tissue metabolism and others, still, the poisons elaborated by bacteria. The evidence upon this subject was briefly reviewed, especially with reference to the toxicity of the blood, the urine and other tissues in various conditions. The toxic substances themselves were classified as follows:

1. Those which though normal to the blood and urine in certain quantities, become toxic when in excess. In such conditions there is an intoxication of the nervous system from the mere accumulation of tissue waste.

2. Substances which are present in the various diathetic insanities, some of which in small quantity are normal to the urine, while others are entirely new and foreign.

3. Substances which result from disordered visceral action. Regarding these we have but little definite information. Enough is, however, known regarding the diseases of the kidney and diseases of the liver to indicate that the insanities associated with these conditions are in all probability the result of auto-intoxication.

4. The toxic substances absorbed from without (excluding all poisons ingested as such). From much that we know we have reason to infer that in certain pathologic conditions poisons are formed in the stomach and intestines which react profoundly upon the nervous system.

5. Toxins which are elaborated by bacteria.

The various intoxications of the nervous system resolve themselves into two great groups, first, the auto-intoxications properly speaking which embrace, first, the substances normal to the blood and secretions but present in excess; then, those substances due to general disturbance of tissue change which we meet with in diathetic conditions; and, last, the poisons formed by the disordered action of special viscera.

In the second group we have those substances absorbed from the intestinal tract, some of which are produced by disordered chemic action and morbid fermentation, and others which are normally excreted by the intestinal tract but now re-absorbed; then we have the poisons which are the direct results or accompaniments of infection. It was further pointed out that the various symptom groups which we recognize as forms of insanity may result from the most diverse agents.

A plea was then made for the establishment of laboratories in hospitals for the insane, in which not only microscopic studies based on the methods of Golgi, Cajal and Andriezen might be made, but in which also the chemistry and the physiologic action of the various toxic substances existing in the blood, urine and tissues of the insane could be experimentally studied. Such investigations would be of great practical importance. They would enable us in the first place to treat insanity more intelligently, and indirectly would diminish the expense of the maintenance of the insane by the State.

DR. S. SOLIS-COHEN, of Philadelphia, gave in detail the "Modern Method of Diagnosing Gastric Lesions."

DR. G. G. GROFF, of Lewisburg, on "Typhoid Fever and its Relation to Filth," showing the great need of more care as to the contamination of wells, cleanliness in the dairy, etc.

DR. EDWIN ROSENTHAL, of Philadelphia, read a report of a

SERIES OF CASES OF LARYNGEAL DIPHTHERIA (SO-CALLED  
MEMBRANOUS CROUP) TREATED BY ANTITOXIN, WITH  
AND WITHOUT INTUBATION.

After brief mention of the historical discoveries in bacteriology leading to the latest method of treatment, he gave a

summary of his work. He divided the cases into two groups: one upon whom the operation of intubation was performed, and another group where this operation was not a necessity. In those cases—nine in number, treated without intubation, all recovered. In those cases—eleven in number, treated with intubation, two died and nine recovered; making a mortality of 18 per cent. Combined statistics before the advent of antitoxin, in cases treated by intubation showed a mortality of 72 per cent.; that is, 28 recoveries in 100. Dr. Rosenthal's own statistics in a former paper showed a mortality of 62 per cent., 38 recoveries in 100. In juxtaposition to this, the combined statistics of antitoxin treatment have shown a marvelous reduction in the death rates. Dr. Rosenthal's work was mostly done with Behring's antitoxin though he has used Aronson's, Gibbier's, and McFarland's antitoxin; almost all his cases recovering makes their value equal. The German antitoxin, however, brought quicker reaction than the domestic, and for that reason was superior. Dr. Rosenthal's conclusions are: antitoxin is a specific in diphtheria. In early cases, those seen in one or two days after infection, no death rate should be recorded. In laryngeal diphtheria (the so-called membranous croup) antitoxin is especially indicated. It should be used in every stage or date of the disease no matter how late we see the case; its influence can be proved, for cases of laryngeal diphtheria perish from suffocation long before any toxic symptoms could be manifested. For that reason he strongly urges the necessity of prompt intubation when indicated, even before the injection of the antitoxin. Regarding the use of antitoxin he said: Do not delay or hesitate in this disease because the case is not so bad, or because it might get well without it; but use it at once—the earlier its use, the more certain its success.

DR. HARRISON ALLEN, of Philadelphia, read a paper on

ADENOID GROWTHS OF THE PHARYNX.

In addition to the symptoms ordinarily associated with hypertrophy of the adenoid growth, Dr. Allen described a group of cases in which the obstruction is due, not to a growth being larger than normal, but to a congenitally narrowed naso-pharynx. He laid especial stress upon a third group of cases. For these he proposed the name "adenoid disease," and claimed that it does not excite mischief by reason of its influence, in any way, upon the functions of respiration, or excite catarrhal disease, but that its effects are noted entirely upon the general nutrition of the patient which is always abnormal. He suggested that the relation of these phases of ill health belongs to the same group of diseases with acromegaly and myxedema. He invited attention to the advisability of studying the adenoid mass in connection with the pituitary body and pineal gland, and made the request that in all cases of death of children, who are known to suffer with adenoid growth in addition to the cause of death, that the base of the skull embracing the pituitary body and the adenoid of the pharyngeal vault be removed in a single piece and prepared in the usual way for microscopic examination.

DR. F. S. NEVLING of Karthaus read a paper on the "Alcoholic Bath in Eclampsia and Suppression of Urine."

DR. H. F. HANSELL, of Philadelphia, read a paper on "A Clinical Contribution to the Study of the Relation of Convergence to Accommodation." This was a report of a case of divergent strabismus of many years' standing, in which binocular fixation was impossible without the sacrifice of clearness of distant vision. Each eye was practically emmetropic and had no organic defect and either could be used in fixation. There was no assignable cause for the anomaly. The interest of the case lies in the transient power of binocular fixation accomplished only by conscious effort and with the simultaneous contraction of the ciliary muscle by which myopia of 3.5 D. was invariably acquired, to disappear immediately when the divergence of the optic axes was restored. The association of the function of the accommodation with that of convergence where the primary stimulus is directed to the interni instead of the ciliary muscle is thus demonstrated, just as, reversely, normal contraction of the accommodation induces normal convergence and pathologic contraction pathologic convergence, instances of which are exceedingly common and indisputable.

DR. BENJAMIN LEE of Philadelphia, presented an abstract of a paper on the

EMOTIONAL BRAIN.

A recent novel which has commanded general attention contains a vivid picture of a somewhat unusual case of nervous disease. It is very boldly drawn and, with few strokes, the description being not that of a scientist but of an acute

lay observer. I give it principally in the author's words: "A gifted young artist, little more than a boy, of a temperament sensitive, emotional and high strung, receives a sudden and terrible shock, in the loss of the woman whose love he has just succeeded in winning, and whom he in turn loves to distraction. An outburst of stormy and semi-maniacal rage followed the discovery." . . . "And finally he gasped, screamed and fell down in a fit on the floor." . . . "Little Billee's attack appears to have been a kind of epileptic seizure. It ended in a brain fever and other complications—a long and tedious illness. . . . At the end of a few months spent in his native village, his health returns, he takes his part in the social life of the village, and awakes one morning to find himself famous, his pictures painted while he was in Paris having achieved a distinguished success." . . . "But one thing constantly preoccupied and distressed him—the numbness of his affections." . . . "It was as though some part of his brain, where his affections were seated had been paralyzed, while all the rest of it was as keen and active as ever."

His own diagnosis of his case occurs in a monologue held with an amiable dog of the name of Tray. "Wait," he says, "till you get a pimple inside of your bump of—wherever you keep your fondness, Tray. For that's what's the matter with me—a pimple—just a little clot of blood at the root of a nerve, and no bigger than a pin point." Thus much for the clinical picture. What shall we say as to the diagnosis made by the patient? To a certain extent it is correct. There is a lesion of an important nerve center. It may be, in his unscientific language, "a spot, or knot, or a blot, or a clot." We often come no nearer an accurate description of a pathologic condition which is paralyzing this nerve mass. But he mistakes in locating it in either the cerebrum or the cerebellum. For every human being has two brains; a thinking brain and a feeling brain; a rational brain and an emotional brain; a brain which ponders, and calculates, and schemes, and records impressions of the outer world; and a brain which loves and hates, rejoices and grieves. The rational brain is situated in the cranium; the emotional brain in the abdomen. In common parlance we speak of their respective functions or manifestations or resultants as mind and heart. As anatomists we know that the heart, being simply an ingenious pump, has nothing to do with the case—any more than "the flowers that bloom in the spring." The particular viscus from which the affections emanate and which was the seat of Little Billee's malady, is the solar plexus, composed of the two semi-lunar ganglia, with the wonderful interlacement of nerves and tissues and ganglionic enlargements which bind them together, and at the same time associate them with the sympathetic and cerebro-spinal nerves and ganglia. The old anatomists showed a correct appreciation of its importance in naming it the solar plexus, for it is indeed the sun of the system, radiating light, warmth and joy to its remotest parts.

What do we know of this important organ? Little enough. It is probably safe, however, to attribute principally to its abnormal action or condition, three, by no means uncommon and very intractable affections, hysteria, melancholia, and hypochondria. Of acute diseases the only one which we can reasonably consider as directly affecting the solar plexus is epidemic influenza, and I know of no other way of accounting for the protean manifestations of that malady, and for the profound and abject despair which is so constant a manifestation of it.

If we know little of the pathology of this organ, we know still less of its therapeutics.

Physics, rather than physic, however, must furnish our armamentarium for the treatment of disorders of this important nerve center. The imponderables—light, heat, electricity, and that which includes, involves and evolves them all, motion, are the agents on which we must place our main dependence.

Motion is administered in the form of exercise in its ordinary sense, of Swedish movements and of massage. In cases in which the patient is unable to take the ordinary exercise, the movement cure provides an admirable substitute, affording us the advantage of exercise without the expenditure of nerve force. This should always be accompanied by massage, and, indeed, in a large number of cases the latter alone can be resorted to. Its application includes the four well-known divisions of kneading, stroking, friction and percussion, which should be varied to suit the requirements of each particular case. The form known as vibrations is of special service in these conditions. They may be applied either by the hand of the manipulator or, much more effectively by means of a machine constructed for the

purpose. In this way, vibrations of excessive rapidity may be communicated to any part of the body for any required length of time. The abdomen, epigastrium and dorsum are the proper points for application in the affections under consideration. This therapeutic means produces a profound impression on the nutrition and the cellular activities of the nervous tissues, and should therefore, like galvanism be used with caution and discretion.

My object in bringing this subject before the society has been to call attention to a neglected and, as I believe, fruitful field of research, and to urge upon those who have the time, the facilities and the training, the importance of losing no opportunity of prosecuting microscopic and laboratory investigations into the pathology and the cellular affinities of the great solar plexus.

"A Contribution to the Study of Deaf-mutism," was given by Dr. A. A. Bliss, of Philadelphia. An examination of the ears, together with a study of the personal and family histories of 546 deaf mutes, pupils in the Pennsylvania Institution for the Deaf and Dumb, indicates that strictly congenital deaf-mutism is a far from common condition. On the contrary, the finding in this large series of cases indicates that loss of hearing in the majority of instances resulted from inflammation of an early infancy origin. Resulting from such processes we find three conditions of the ears: 1, a slow, non-suppurative, sclerosing process, which has immobilized the sound conducting apparatus; 2, a condition of sclerosis after suppuration, the drum head being destroyed in varying degree and the mucous lining of the tympanic cavity changed to a dermoid or fibrous tissue; 3, a suppurative process, still active, which has caused simply a chronic otorrhea without much loss of tissue, or may have caused total destruction of the drum head, exfoliation of the ossicles, necrosis of the tympanic wall and the development of cholesteatoma. Consanguinity of parents must be recognized as a causative element in deaf-mutism, but is not peculiar in any special liability to cause serious affections of the ears in the children of such unions. In such instances, deaf-mutism is simply one of the manifestations of physical degeneration, just as phthisis, idiocy, epilepsy, cretinism, insanity and functional or organic abnormalities in the cerebro-spinal or lymphatic systems may also be manifestations of a physically degenerate race. The examination, in addition, indicated that a tendency may exist in certain families to develop aural disease attended with deafness more serious and profound than would commonly follow such conditions in more normal individuals. Thus one-fifth of the entire 546 pupils had deaf-mute relations, and in some instances belonged to families all of whose members were deaf mutes. The results of the examination favor the belief that in a vast number of instances the recognition of otitis media, originating primarily or as a complication in other diseases, occurring in infancy or in early childhood, and the proper treatment and after treatment of this aural condition, would have preserved the hearing of many of the 546 pupils and would have saved them from becoming deaf mutes.

(To be continued.)

#### Rhode Island State Medical Society.

*Eighty-fourth Annual Meeting held at Providence, R. I., June 6.*

The meeting was called to order by Dr. Robert F. Noyes, and the recording secretary, Dr. W. R. White, announced as the result of the annual election of officers the following:

President—Elisha P. Clark, Hope Valley.  
First Vice-President—William A. Gorton, Providence.  
Second Vice-President—Francis H. Rankin, Newport.  
Recording Secretary—Frank L. Day, Providence.  
Corresponding Secretary—George D. Hersey, Providence.  
Treasurer—George L. Collins, Providence.  
Censors—J. W. C. Ely, Benjamin Greene, Eugene Kingman, J. H. Morgan, G. W. Jencks, H. G. Miller, W. R. White, F. H. Rankin.  
Board of Examiners—Franklin M. Eaton, Fred T. Rogers, Herbert Terry, Frank L. Day, John W. Keefe.

#### STANDING COMMITTEES.

Of Arrangements—E. F. Walker, J. W. Keefe, F. E. Peckham.  
On Publications—G. D. Hersey, C. M. Godding, G. T. Swarts.  
On the Library—H. G. Miller, G. D. Hersey, G. W. Porter, G. L. Collins, F. L. Day.  
On the Museum—W. J. McCaw, G. T. Swarts, F. B. Fuller, C. M. Godding, S. A. Welch.

On Necrology—E. Kingman, C. H. Leonard, H. C. Miller. Auditor—F. H. Peckham Jr.

DR. GEORGE L. COLLINS presented the annual report of the Trustees of the Fiske Fund, giving a record of the meetings held and the financial condition. The amount of the fund is \$9,532.58, and the amount at the disposal of the committee is \$959.52. No premium has been awarded this year, as no essay has been received. The subject proposed for 1895 is "The Etiology, Pathology and Treatment of Diseases of the Prostate Gland." The premium offered is \$300.

The society decided that Providence should be the place of the next meeting.

The deaths of Peter H. Madden of Woonsocket and Frank L. Forsyth of Providence were announced.

DR. T. D. CROTHERS of Hartford, and DR. E. H. DAVIS of Plainfield, were introduced as delegates from the Connecticut Medical Society. They spoke briefly. Dr. Newman of the New York Society was also introduced.

DR. WHITE read the report of the censors' meeting held earlier in the day.

DR. CHARLES H. LEONARD opened a discussion on the nutrition of the very young child. Dr. J. W. Mitchell followed.

DR. FREDERICK T. ROGERS read the essay entitled "Humbug as a Therapeutic Agent." He showed that superstition had ever had an important effect on human affairs. Likewise, medical theories, now exploded, had a beneficial effect in their day. They have had a good effect, both subjectively on physicians and objectively on the patients. Certain alcoholic cures were, he said, undoubtedly, humbugs. Whether these effects were due to hypnotic influences, the effect of a powerful mind over another, or to the giving up to nature and allowing her to do her own repairing, the Doctor could not say, but the facts showed there was need of less use of drugs and more attention to the nature of diseases. The physician was advised to go to the quack for example upon this point.

The Annual Address by DR. GEORGE F. KEENE was upon "Some of the Phases of Alcoholism." In introduction he said that the Legislature that passed a bill to suppress quackery had at the same time had under consideration an appropriation to promote quackery in the liquor cure bill. To alcoholism, side by side with syphilis, were ascribed the greatest pathologic effects. Alcohol was designated as not a real, but a supplementary food. Its effect was greatest upon the brain. It is the genius of degeneration. Effects were specified upon the various parts of the nerve and arterial systems, and symptoms of alcoholism were described at length. The hearers were warned against the worship of the "golden" calf of Keeley.

At the conclusion DR. NOYES introduced the new President of the Society, DR. E. P. CLARKE, of Hope Valley, as one ripe in years, rich in experience and loyal to the Rhode Island Society. In assuming his new office Dr. Clarke briefly replied.

A vote of thanks was extended to Dr. Noyes for the able manner in which he had performed the duties of President for the past two years.

The annual dinner was held in the Trocadero following adjournment. The unusually large number of 140 was present, including one lady member of the society. Dr. George L. Collins acted as anniversary Chairman. The speakers were Dr. E. P. Clarke, of Hope Valley, who Thursday began his Presidency of the Society; Gov. Charles Warren Lippitt, Samuel R. Dorrance and Prof. H. C. Bumpus, of Brown University.

DR. CLARKE spoke of the profession of the country doctor, to which class he considered himself to belong. He said they were the hardest worked and poorest paid in the profession. A great physician was allowed to profess ignorance of a particular case, but the country doctor must know everything. Therein many of necessity fail. In spite of his place in this class, he expressed the hope that the society would not lose ground during his term of office and asked for their sympathy and support.

GOVERNOR LIPPITT praised the society for its financial management of the Fiske fund, whereby it had increased 600 per cent., congratulated it for securing the passage of the bill to regulate the practice of medicine, and paid a tribute to the physicians who accompanied the soldiers to the battle field. The State should be proud of the medical profession of Rhode Island.

SAMUEL R. DORRANCE was asked to speak for the Rhode Island Hospital. He is a former President and Secretary of the corporation, and at present a member of the Board of Trustees. He said that the origin of the hospital was among the men of this society. In the face of poor success at first,

they stuck to the project. Even after its establishment the people looked upon it as a place where doctors tried experiments. But there are now many evidences that the community realizes the value of the institution. The present condition is due to the men of this society in giving their time, best thoughts and fruits of experience without price to the work.

PROFESSOR BUMPUS of Brown University, outlined the work that is being done for medical students at Brown, the increased appropriations making possible greater laboratory facilities, better apparatus, and more books. Applications for the courses are increasing. He thanked the members for their help to the college.

During the afternoon the Fellows and guests visited the St. Joseph's Hospital, and were there tendered a reception.

## NECROLOGY.

ARTHUR E. DURHAM, F. R. C. S., Eng., Consulting Surgeon to Guy's Hospital, died May 7, aged 61 years, after a short illness, from acute pneumonia. He was a native of Northampton, and entered Guy's Hospital in 1855. After distinguishing himself in the examinations at the University of London he took his Fellowship at the Royal College of Surgeons, England, in 1860. Two years later he was elected to the post of assistant surgeon at Guy's, and from 1873 to 1894 he was one of the full surgeons at the hospital. On his retirement in 1894 he was appointed one of the consulting surgeons of the institution. In the medical school attached to the hospital he lectured for many years on anatomy and surgery. He took a prominent part in all the movements which had for their object the welfare of the students. He was President until last year of the Students' Club, and of the Guy's Hospital Cricket Club. Mr. Durham's contributions to the literature of his profession were almost entirely limited to papers read before the societies, and articles to "Guy's Hospital Reports," Holmes' "System of Surgery," and Quain's "Dictionary of Medicine." In the former were published his valuable observations on "Sleeping and Dreaming," and the "Physiology of Sleep," in which were recorded his memorable experiments to show the state of the circulation in the brain during waking and sleeping. Mr. Durham was one of the first surgeons in this country to take up the specialty of diseases of the throat and nose, and he was the designer of the lobster-tail tracheotomy tube which bears his name. As an operator he was bold, neat and skillful. Nature had endowed him with hands which must have been the envy of most surgeons who knew him; the fingers were long and tapering, as flexible as those of an accomplished musician, and full of grace of movement. At the time of his death Mr. Durham was a member of the Council of the Royal College of Surgeons, England, upon which body he had served eleven years. In former years he served as vice-president. Mr. Durham was exceptionally well and favorably known to American surgeons.—*London Medical Press*, May 15, 1895.

SAMUEL PATERSON VON DER SMITH, M.D., of Bloomfield, N. J., died Friday, the 31st ultimo, of tubercular enteritis. He was born in Lancaster, Pa., in March, 1821, and was graduated in medicine from the now extinct school, the Philadelphia College of Medicine and Surgery, in the class of 1849. For several years he practiced medicine in New York. He was examining surgeon of the New York Police Department for some time, and later was an examining physician of the Mutual Life Insurance Company. At the opening of the war he was a surgeon in the 6th New York Cavalry, and afterward he was with the 16th New York Cavalry. He served through the Rebellion. Dr. Von der Smith was in Washington when President Lincoln was assassinated by John Wilkes Booth. He went with the party that chased the assassin across the Potomac into Virginia, and was present when Booth was shot. He never tired of describing the scene. He received a medal and a diploma for the part he took in running Booth down. After the war Dr. Von der Smith went to Arizona, and was attached to one of the regiments on the frontier as regimental surgeon. He was acquainted personally with Generals Grant, Sherman and Sheridan, and he was a member of Cameron Post, No. 79, G. A. R., of New York City. He had lived in Bloomfield ten years.

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JUNE 15, 1895.

MORTALITY AND CAUSES OF DEATH IN MEDICAL MEN.

DR. KORTRIGHT has recently presented this subject in the *Brooklyn Medical Journal*, bringing out some very impressive and suggestive facts. He made a study of the mortuary records of four hundred and fifty physicians who lived and died in New York and Brooklyn, and the vicinity, during the past eight years. As the surroundings and climate were alike generally, the facts are of unusual interest. The average age of death was 54.6 years, and the mortality was 25.53. This mortality is only exceeded by saloon keepers, butchers, quarrymen, and poor factory operatives. Clergymen have a mortality of only 15.93, and lawyers 20.23, so that the practice of medicine is far more hazardous and perilous as an occupation.

Among the causes of death, suicide is four times more common among physicians than other adult males. This includes many cases of accidental poisoning, such as an overdose of some drug used by the victim, either addicted to the drug, or using it for some special purpose. Others died from bullet wounds of the head, the motive of which was not clear. Consumption was a very small factor as a cause of death, reaching only 10 per cent., while the ordinary death rates among adult males in New York are 19 per cent of the whole number. Physicians have less than half the usual mortality from this cause.

Deaths from the latest fad, appendicitis, were one thirty-seventh of the whole, showing that physicians are not suffering from this trouble in the same ratio as other people. Typhoid fever appears to be exceptionally high as a cause of death; 4½ per cent. died

from this cause. The usual rate among adult males is 1¼ per cent. Pneumonia furnishes a high death rate, 13 per cent; in the adult male population the mortality is 14 per cent. Bright's disease, apoplexy and various forms of heart disease are grouped together as all having common pathologic conditions, viz., arterial sclerosis and degeneration of the muscular fibers. The mortality from these causes was 35 per cent., whereas the usual death rate from these causes among all male adults is only 25 per cent.

The conclusion is clear that these are the most common diseases that prove fatal among medical men. Arterial sclerosis was the cause of over a third of all the mortality. This is confirmed by English statistics. This means, briefly, that irregularities of the heart's action, from neglect of diet, sleep, nutrition, overeating, undereating, overwork and under exercise has left its impression in the thickening of the walls of the heart and arteries. The constant variation of the tension of the arteries has resulted in fibrinous deposits and inflammatory changes involving the kidneys, as well as the heart and arteries. Probably, defects of elimination are among the most common early causes of irritation and changes. This is followed by poisoning and starvation and increased functional activity of the heart in the effort for elimination. Then follows changes in the specific gravity of the blood from the retained products of metabolism and pathologic conditions which are expressed in the term arterio-sclerosis.

It is the irregularities of living which make the physician neglect many hygienic rules that he forcibly impresses on his patients. He is often eloquent in his arguments and reasons for rest and change, and regular hours of sleep, to those who consult him. But, alas, he does not put into practice in his own case what he so urgently impresses upon others.

Physicians keep on, long after warning voices are heard of approaching dangers. Voices of palpitation, of arterial tension, of tortuous arteries and increased flow of limpid urine, and other unmistakable signs; voices of insomnia, indigestion, morbid anxiety, slow restoration when exhausted, loss of ambition and interest in things of the present. These voices tell of the approach of the end. There is only one way open for the future and that is to give up night work, and confinements, take a long summer rest, eat abstemiously, stop all drinks except water and tea or coffee, take exercise in the open air, and give careful attention to the function of the skin, avoid chills and worry and mental care and strain, and live carefully and quietly. Take this course, and we may expect to live many years and be of great service to those about us. Here is an open field for new studies—how to prolong and raise the life work of physicians.

## ALCOHOLIC COMA, ON THE STREET.

This JOURNAL in its editorial columns has frequently called attention to this subject, and DR. L. D. MASON, of Brooklyn, N.Y., recently read a paper before the Kings County Medical Society, calling attention to the frequent blunders made by policemen and ambulance surgeons in placing all cases found stupid on the street with an alleged alcoholic breath, in cells of station houses. DR. JOHN MORRIS, of Baltimore, Md., discussed this subject in the State Medical Society of Maryland seventeen years ago in a very clear paper. Curiously, this failed to attract much attention in this country, but was translated and reprinted in many of the leading journals of Europe.

The French Academy of Medicine took up the subject, and as the result of a very wide discussion, special laws were made, requiring all cases found stupid on the street to be taken to a receiving hospital where they could be examined and observed. In London, the police were directed to take such cases to special emergency hospitals. In many of the cities of the continent, similar rules have been enacted. In New York and all the large cities and towns of this country, the diagnoses of such cases are made by the police and ambulance surgeons, or any one who may be passing. The result is that a considerable number of these cases are found dead in the cells next morning. Where an autopsy is made, hemorrhage, tumor of the brain, fracture of the cranium with concussion, Bright's disease, sunstroke, embolism, and other physical lesions are discovered. If an inquiry is made into the history of the case, epilepsy, narcotic poisoning and heat or sunstroke appears. For various reasons, spirits were taken shortly before the coma came on, and the breath determined the diagnosis. These cases are treated roughly in the ambulance or patrol wagon, and with the slightest appearance of opposition are struck on the head, or shaken violently, to intimidate and keep them down. Thrust into a cell to sleep off the supposed stupor of alcohol, the patient dies from neglect, and next morning the police surgeon certifies to death from alcoholism. The case is recognized as a man of prominence and temperate, and an autopsy reveals the real condition. There is no redress, and this is repeated in almost every city in the Union. One week in August, last summer, five cases occurred in New York City. These persons died in cells of the station houses, from hemorrhage, embolism and Bright's disease.

DR. MASON's paper was an earnest protest against this practice, and he gave numerous facts and cases showing the great wrongs committed by having the diagnosis of such cases made by persons unfit and incompetent to judge.

The Kings County Medical Society appointed a committee and passed resolutions, calling on the

Health Board to make special provisions against this evil. As a result the Health Commissioner of the city of Brooklyn has ordered that all cases of coma found on the street must be sent to the hospital. The wisdom of this was clear the next week after this rule went into effect, in the diagnosis of acute alcoholism made by an ambulance surgeon, of a case which proved to be one of fractured skull.

DR. MASON read before the Neurological Section of the ASSOCIATION at the Baltimore meeting, another paper on the same subject, which was followed by a resolution urging physicians to petition authorities in all cities to have these cases of coma cared for rationally. This paper and resolution will appear later in the JOURNAL. Thus the good work of DR. MORRIS in 1878 which bore fruit in Europe, is now taken up by DR. MASON, and will inaugurate a genuine reform all over this country in the near future.

The criminal recklessness of the present practice was recently illustrated in Philadelphia, where the police brought into the station a stupid, half-delirious man as drunk. The next day he was found dead, and proved to be a clergyman, under treatment for Bright's disease, who went out for a walk, and probably took spirits for weakness, and was arrested and hit over the head by the officer. In a list of cases of this character is one of a prominent physician who was found dead in a station house cell. His skull was fractured and the police record was "drunk and stupid." He was a thoroughly temperate man, had not been robbed, and was seen in his usual health an hour before the arrest by the police. The inference was that for some sudden illness he had taken spirits, and his skull had been fractured by blows of the officer at the time of the arrest. Our readers will recall many similar cases and recognize a radical reform in the present practice.

## RHODE ISLAND MEDICAL SOCIETY.

The eighty-fourth annual meeting of this society occurred at Providence, June 6, a detailed notice of which appears in this JOURNAL. This society differs from other State societies in many respects, and has done some excellent work in scientific medicine. Practically, all parts of the State are within an hour's ride of Providence, so that all physicians can attend the meetings which are held four times a year. These meetings open at 10 A. M., and after the informal relation of cases, an essay and address follows, then a dinner and adjournment.

The intellectual exercises are confined to two hours, and the dinner another hour or more; the whole not exceeding four hours, and the physician is home again in time for evening practice.

The State is densely populated with a succession of manufacturing villages and cities, and physicians have to do all-round practice of every sort. The

surgery from the mills, and the fevers and epidemics of these villages, with faulty water supply and bad sewers, and a most changeable climate, along the bays and numerous rivers of the State, bring a variety of medical work that requires great versatility not common in other States, for "State" medicine or "sanitary medicine" is as much a medical specialty as ophthalmology or laryngology.

Recently an act regulating the practice of medicine has been passed, requiring an examination of all physicians without a diploma from schools which did not require four years' instruction, and a certain preliminary training after July, 1895. In all cases of persons now practicing, a diploma, and evidence of respectable honorary practice from 1892 is required. This act is regarded with great favor as the beginning of better legislation in the future. Many parts of the State have large seaside summer villages of immense populations in the warm weather, and irregulars of all descriptions gather here. This practice act will do much to drive out this class who live on the credulity of their patrons.

Although in close proximity to Boston and New York, the Rhode Island physicians have retained the original Quaker independence of thought and action that has always marked the people of this State. Grave questions in surgery and general practice are largely settled at home by local experts, and the distant consultant is rarely seen. New medical works always have a large sale in this State, and the State Society has accumulated a very large library which is open to members.

Three years ago a medical monthly was started in Providence, which has now become a weekly. It is edited by a large number of local and foreign physicians, and has the promise of being a very noted journal in the future. A most commendable feature of the Rhode Island Medical Society meetings, is to have only one or two papers, and give the author ample opportunity to present the subject fully and clearly. In the meeting mentioned, DR. ROGERS' essay on "Humbug as a Therapeutic Agent," discussed the credulity and superstition which has been associated with medicine for ages. He mentioned some of the great medical superstitions of the past, now exploded, which had a beneficial effect, both subjectively and objectively on the physician and his patients. He cited the alcoholic cures of the day as examples of quackery doomed to an early death.

The annual address by DR. KEENE treated of the "Drink Problem," and the need of a medical study of cases which now come under the care of quacks. He called attention to the boldness of the "gold" curers, who had come before the Legislature claiming recognition, particularly asking the State to assist in promoting quackery of the worst form. Both the essay and address were admirable discussions of topics

that every physician should be familiar with, and be able to teach authoritatively to his patrons.

It is undoubtedly true that physicians do not give sufficient attention to mental therapeutics and the essentials, to inspire the confidence and trust of their patients, and thus neutralize some of the credulity which supports mind cures, gold cures, drug cures, faith cures and other 'isms. The coming physician will make use of many of the means now despised, and accomplish results now deemed impossible.

#### THE MICHIGAN STATE MEDICAL SOCIETY.

The thirtieth annual meeting of the Michigan State Medical Society was held in Bay City, Mich., June 6 and 7, under the presidency of DR. H. O. WALKER. The attendance was representative in character and equal to the average in numbers. The local committee had made abundant provision for the convenience of the members, and with tireless endeavor promoted cordial goodwill, so that the meeting was without friction in any respect.

It was gratifying to have the committee report the enactment of a law by the Michigan State Legislature to prevent blindness, by compelling attention to the purulent ophthalmias of the newborn, but sadly disappointing to learn from other committees that the bill to regulate the practice of medicine failed to become a law—after the manner of many previous attempts, and that the bill to secure a registration of births and deaths in accordance with common sense, had also failed to become a law. Michigan, still, by deliberate act of its Legislature, remains the dumping ground for the world's incompetent and dishonest doctors.

The society made a notable change in its requirements for membership, in that it admitted two physicians whose entire medical education was obtained in "homeopathic" medical colleges. It was stated by a member upon the floor of the house that such action was contrary to the Code of Ethics, so that the action was taken deliberately and with full knowledge of the facts; a fact the more noteworthy because last year this society refused to entertain the idea of changing the Code of Ethics in any particular.

The scientific work of the society is done in three sections. These were all well attended, the papers of scientific and practical interest, and intelligently discussed. As the papers numbered fifty it will be apparent that the sessions of two days and one night were needful in order that the work be accomplished. The arrangement of the first session of each of the sections was peculiar, in that it was devoted to the consideration of a series of papers discussing different phases of a single topic; thus the surgical section discussed urethral surgery; the medical section diphtheria, with the antitoxins; gynecology, malig-

nant diseases of the uterus. The papers prepared for these several discussions were of unusual merit. The remaining sessions of the sections were devoted to papers on widely diverse subjects, usually embodying original studies or original research, and of such general attraction as to hold the members in attendance till the time for final adjournment. Since the organization of these sections this society has been singularly free from wire pulling and disagreeable episodes. There are several reasons for this delightful change from former days: 1, there is nearly four times the amount of work called for, which engages at least four times as many physicians. This employs the surplus energy so that less is left for less useful purposes; 2, there are four times as many officers, so that the desire for office-holding is more largely appeased, and hence the diminished struggle for such positions; 3, an atmosphere of scientific study and work is created, of far greater intensity, and this represses much that is undesirable which was associated with the old style medical convention; 4, engaged in actual work constantly to a number threefold more than formerly, the members have found a pleasure and satisfaction hitherto unknown; 5, each member had a chance to select one of three papers or discussions at any time during the meetings—so that he had an opportunity to select topics hitherto unavailable; 6, the papers have become more scientific, and are prepared with greater care, because the selected audience has a chance to criticise more intelligently, and by its very selectness is better able to criticise.

It must be admitted that this new state of things is unsatisfactory to the friends of the old time medical convention. These prefer a chance to talk to a large crowd; to have a less discriminating audience; to shut off others from a chance to learn the art of public speaking in medical societies—they do not enjoy the highest grade of scientific work. However, it is hoped by the majority of thoughtful workers in the Michigan medical profession that the present system may be continued and perfected.

Mt. Clemens was selected as the next place of meeting, and the first Thursday in June, 1896, as the date for holding the same.

#### THE INDEX MEDICUS.

The following notice from MR. GEORGE S. DAVIS will be received by the entire profession with great regret. No one, however, can criticise MR. DAVIS for declining any longer to make good the large discrepancy between the expenditures and the receipts.

In our opinion the ASSOCIATION can afford to print this work as soon as the subscription list of the JOURNAL shall reach 12,000. With a subscription list of that number, including members of the ASSOCIATION, the increase of advertising would pay for

the loss in the issue of the *Index Medicus*. It seems entirely clear that no private publisher will be willing to stand the loss, and as the work is universally conceded to be of the greatest utility to medical writers and teachers, it would seem eminently fitting that our great ASSOCIATION should carry it on. But with the depleted revenue that we must probably face this year, on account of the necessary elimination of certain advertisements, such increased expenditure would be impossible unless every member puts forth his efforts to bring up the subscription. We have not found canvassers of much benefit. Most doctors are too busy to talk to them, and it naturally results that the only real growth of the power and influence of the ASSOCIATION will be made when the members, each for himself, resolves that the old ASSOCIATION shall be the greatest on the globe, and secures a new member or subscriber for the JOURNAL.

The new volume begins July 1. Let every member obtain one new member or subscriber to start the new volume on a better and higher plane than ever. With the consent of the editors of the *Index*, and the vote of the ASSOCIATION at its next meeting, not only may the *Index Medicus* be preserved, but the ASSOCIATION itself, ever foremost in work for the advancement of our profession, may still further promote its noble aims and purposes.

#### THE PASSING OF THE INDEX MEDICUS.

"DETROIT, MICH., June 7, 1895.

Dear Doctor:—I notify you, as a subscriber, that the *Index Medicus* terminated its existence under my supervision, with the April number. I have published this journal since January, 1885, at an annual loss of from \$500 to \$1000, in view of my interest in a purely scientific publication, in which I had no mercenary interest whatever. This is a larger sum than has been contributed by any professional man, or body of professional men to this purpose.

Owing to the hard times of 1893 the subscription list of this journal was greatly shrunken, and difficulty was found in making collections from subscribers. The deficit in 1893 was a very material sum, which was largely increased in 1894. Announcement was then made to the medical profession that unless the subscription list of the journal could be placed upon a paying basis I must discontinue its publication. Many friends of the *Index Medicus* appealed to me to defer action until they could by individual and organized effort arrange for an increased number of subscriptions, or for a fund whereby its continuance might be assured. After a period of six months it is found that the prospective deficit this year, assuming that all subscriptions are collectible, will be nearly \$2,000. Inasmuch as I can not afford to carry such a burden I have decided as above announced.

Very sincerely yours,  
(Signed) GEO. S. DAVIS."

#### PAN-AMERICAN MEDICAL CONGRESS.

PRESIDENT DIAZ in his annual message to the Mexican Congress, April 1, 1895, says:

"The Executive, being determined to omit no effort or spare no expense which might redound to the honor of the Nation and to the advantage of studious youth, has created an Anatomia-pathologic Museum, with the double purpose of furnishing a new and efficient element of instruction to the school of medicine, and also for the purpose of appreciating worthily the scientific labors that are to be presented to the second Pan-American Medical Congress when it meets in this Capital in 1897."

## CORRESPONDENCE.

### "Audi Alteram Partem."

SAN FRANCISCO, CAL., May 22, 1895.

To the Editor:—[Our esteemed correspondent, whose letter pronouncing the collective investigation of the antitoxin treatment of diphtheria impossible of execution was published in the JOURNAL of May 11, takes exception to the summary fashion in which his first communication was treated, and furnishes the following argument in support of his belief that the results of such investigation must be valueless.]

I feel perfectly safe in saying that, in the present light of science, no living person can make a positive differential diagnosis between typical Bretonian diphtheria and allied affections—and for the following reasons:

1. A schizomycete answering (Löffler's) description has been found in less than 50 per cent. of cases of clinical diphtheria—and then never alone, always together with other forms, such as streptococci, staphylococci, pneumococci, bact. coli communis and micrococcus prodigiosus (See Hausmann, Benda, Ritter, Körte and others. Proceedings Berlin Medical Society, Nov. 28, Dec. 7, 12, 1894; also report of New York Board of Health on the bacteriologic investigation of 6,511 cases of clinical diphtheria between May 4, 1893, and May 4, 1894).

2. This virulent bacillus has been found in the mouth and throat of perfectly healthy children, and nurses in diphtheria wards. Also in connection with cases of rhinitis fibrinosa running the same clinical course as other cases in which it was absent (Benda, Liebreich, Hausmann, Ritter, Unger and others. Proceedings Berlin Medical Society, Nov. 28, Dec. 7, 12, 1894).

3. The disease produced in the lower animals by injections of so-called pure cultures of Löffler's bacillus diphthericus, differs radically from typical Bretonian diphtheria in human beings (Hausmann, Ritter, Benda, Scheinman, Unger, Scholz and others. Proceedings Berlin Medical Society, 28, Dec. 7, 12, 1894).

4. Ritter found bacilli absent in a case of typical Bretonian diphtheria.

5. Polymorphism of schizomycetes, such as the bact. coli communis and others common to the alimentary canal of human beings and the lower animals—and constantly found within the internal organs of diseased organic forms before and immediately after death—render a scientific bacteriologic diagnosis impossible. (See reports on the following poison epidemics: 1, at Frankenhausen, investigated by Professor Gartner; 2, at Rürsdorf, investigated by Gaffky and Paak; 3, at Moorsule, investigated by Van Ermengen; 4, at Cotta, investigated by Nulsen, Zohne and Gartner; 5, at Ganstad Insane Asylum, investigated by Peter F. Holst. Also Wurtz and Hermann, Macaigne, Welch of Baltimore, Lubarsale, Tavel, Roux, Escherich, Fraenkel, Dunbar, Rodet, Stocklin, Cohn, Lankester, Billroth and others. Duclaux

writes in *L'Annales de l'Institut, Pasteur*, 1891, page 350): "*Chaque année de travail fond ensemble des espèces, qu'on croyait distinctes et en sépare d'autres, qu'on croyait identiques.*"

(Each year's labor removes us farther from the hope of distinguishing and separating from one another "forms" thought to have been identified.)

Serum-therapy is entirely "empirical," inasmuch as leading investigators in this field differ widely in regard to the *modus operandi* of "immunity," said to occur in connection with organic forms having passed through so-called "infectious diseases" and it can not be said that any of these theories, which may be enumerated as follows, has stood the test of severe adverse criticism: 1, Pasteur's exhaustion theory; 2, Chavau's retention theory; 3, Metschnikoff's phagocytosis theory; 4, Buchner and Hankins alexin theory; 5, Koch-Behring antitoxin or chemic theory. All of these theories are stubbornly adhered to by their respective originators.

Antitoxin serum-therapy is essentially the outcome of the violent opposition offered by Koch and his disciples to Metschnikoff's phagocytosis teachings—chemic or humero-pathologic processes versus Virchow's intra-cellular processes—and while many things point toward the latter, still there exist no scientific data corroborative of any theory, and any therapeutic method based thereon is unscientific—empirical as it were. For an exhaustive treatise on the various theories, experiments and data leading up to the introduction of antitoxin blood serum into human therapeutics, see my paper, "The Status Presens of Antitoxin Blood Serum," read before the State Medical Society of California April 16, 1895.

For reasons too obvious to mention, antitoxin diphtheria serum has been more thoroughly tested in Berlin where it originated than elsewhere, and inasmuch as leading unbiased Berlin physicians have tested its merits during the past five years, and expressed their views thereon professionally, we are in a position to judge correctly of the matter.

In the Berlin Medical Society, Nov. 28 and Dec. 7 and 12, 1894, Hausmann, Ritter, Benda, Unger, Scholz, Liebreich, Oppenheim, Hahn, Meyer, Gottstein and others went on record as saying that, "antitoxin diphtheria serum did neither render immune nor cure diphtheria as claimed by Behring, but that it complicated said disease by giving rise to serious inflammations of important functioning organs such as: the liver, spleen, heart, kidneys, nervous system and skin—the direct result of chemic decomposition of the blood."

Nor does the following mortality statistics, appertaining to Berlin, compiled by Gottstein from the official death register of the city, show the serum-therapy up in a very favorable light when studied attentively and without bias:

From September 30 to November 24.					
Years . . . . .	1890	1891	1892	1893	1894
Deaths in entire Berlin . . . . .	276	216	269	334	209
Deaths in hospitals . . . . .	131	124	178	197	131
Admitted to hospitals . . . . .	328	320	453	454	712
Per cent. . . . .	39.9	38.7	39.3	43.3	18.4
For the entire year.					
Year . . . . .	1890	1891	1892	1893	1894
Deaths in entire Berlin . . . . .	1,591	1,105	1,442	1,627	1,281
Deaths in hospitals . . . . .	682	613	837	956	737

For reasons too obvious to mention, hospital mortality is much less than that of private practice—hence we can readily understand why the mortality from Sept. 30 to Nov. 24, 1894, appears to be reduced to half of that of a corresponding period in 1891, because for some reason, probable panic attendant upon serum notoriety, 712 patients were admitted to the hospitals in 1894 against 320 in 1891. To what extent these 712 hospital cases have been manipulated by the friends of the serum can best be seen by referring to the last columns of these statistics which show: that the mortality from diphtheria for entire Berlin during 1894 up to November 24 far exceeds that of the entire year of

1891—in spite of the fact that over 1,000 children were treated by the serum method in the hospitals, beside numerous cases in private practice. Adding the number of deaths that occurred between November 24 and January 1, the mortality of Berlin from diphtheria in 1894 exceeded that of the year 1891 by about 600, or over 25 per cent.

Rumpf, of Hamburg, states that better results are obtained in the hospitals there by other methods.

Virchow and Baginsky have expressed themselves in favor of the serum-therapy, but inasmuch as the opinion of the former is based upon certain results said to have been obtained by his assistants during a few weeks in the summer of 1894, while he was absent on his vacation—and inasmuch as the latter entirely ignores and defies mortality statistics—their opinions upon this subject can be of little or no value. (See Proc. Berlin Medical Society, Nov. 28, Dec. 7, 12, 1894.)

I will exclude all data coming from Behring, Aronson and others personally interested in the manufacture and sale of antitoxin serum. As a rule, medical men in Europe are very conservative regarding this new therapy—as they have not yet recovered from the humiliating effects of the “tuberculin swindle,” which originated in the same quarters.

So far, nothing has appeared in the American medical press which would indicate that medical men in this country are familiar with the cardinal principles underlying this subject—and I would advise them to “look before they leap,” as perhaps neither “they” nor the “American public” are ready to accept these principles when fully understood.

These principles were exposed by Binz in 1883 at the Budapest Congress for Internal Medicine, when he said: “Our future therapeutic efforts in infectious diseases must be toward ‘*Den lebenden organismen zu entgiften.*’” (To poison the organism, as it were.)

I take issue with Binz and his followers on this doctrine, and I believe that the majority of the American medical profession will continue in the future as they have done in the past—to eliminate the contagium at the bedside. “*Den lebenden organismen nicht zu entgiften-wollen.*” Respectfully,  
CHAS. G. KUHLMAN, M.D.

#### Answer to Dr. Rogers.

NEW YORK, June 10, 1895.

To the Editor:—Dr. Rogers’ attack upon Koch’s demonstration of the causation of cholera, in the JOURNAL of June 8, is rather amusing to the medical man of to-day. While believing that he will receive answers more able than mine, I take the liberty of calling his attention to a few errors in his statement.

In the first place, Koch did not “fancy” that the comma bacillus was the cause of cholera; it had to be present in every case of cholera, it had to be capable of cultivation in artificial media in pure culture, and it had to produce the disease whenever inoculated, before he was willing to identify it as the cause. Unfortunately, the inoculation experiments do not depend alone upon results obtained in the lower animals, for several bacteriologists have themselves been infected while working with this organism.

In the second place, while comma-shaped organisms are universal, as the Doctor states, the comma bacillus of Koch is neither universal nor harmless. If the shape of micro-organisms alone were sufficient to differentiate them, what a simple easy study would be the science of bacteriology! Dr. Koch has never asserted, to my knowledge, that the cholera bacillus is frequently present in water from all sources, although any up-to-date physician knows that curved bacilli are frequently present. All cholera germs are curved bacilli, but all curved bacilli are not cholera germs.

The experiments of Drs. Pettenkofer and Emmerich, as alluded to in the letter, prove nothing, for the following (and other) reasons:

1. Koch and many other observers have shown that acids readily kill this organism; we can easily understand, therefore, how the healthy acid gastric juice of the two physicians protected them from infection. Drinking cholera broth does not necessarily imply infection; it only makes infection possible. The liquid stools mentioned can be produced by toxins isolated from old cultures, without any bacilli being present.

2. Organisms grown on artificial media for many generations are very apt to lose their virulence, even though they may have been very virulent in the first few cultures.

In conclusion, I would hardly advise Dr. Rogers to repeat the experiments of Pettenkofer and Emmerich, as such a communication as he has given us, in defiance of modern scientific research, might indicate that his gastric juice had alkaline tendencies! Yours respectfully,

WALTER G. HUDSON, M.D.

#### A Card from Secretary Atkinson.

PHILADELPHIA, June 4, 1895.

To the Editor:—Your explanation of the inability to send the JOURNAL to the new members does me great injustice. As I wrote you, not any of the credentials nor papers of the Registration Committee have yet reached me. All were sent directly to Dr. Newman, our Treasurer. Had I had the list or my own private index, made especially to prevent this, I would have had my share done at once. For this reason, I ask you to do me the justice to announce in the JOURNAL the fact that all the papers were sent at once to Chicago. I am getting letters on this subject constantly, and it is important that I should be set right before the profession. Please do me this favor at once.

Yours very truly,

WM. B. ATKINSON.

#### Literature on the Dual Brain.

ST. LOUIS, June 4, 1895.

To the Editor:—I have read with interest your editorial on the “Dual Brain,” in a recent number of the JOURNAL. Please inform me how I can procure Dr. Bruce’s article on this subject, also the writings of Holland and Wigand, and Brown-Séquard.

FAYETTE C. EWING, M.D.

ANSWER:—Dr. Wigand, “Duality of Mind,” *Lancet*, 1844; Sir Henry Holland, “*Chapters on Physiology of Mind*,” 1852; Brown-Séquard, Toner Lecture, 1877; L. C. Bruce’s article in *Brain*, Spring No., 1895.

#### Exact Address of Association Treasurer.

CORONADO, CAL., June 1, 1895.

To the Editor:—Will you please insert in our JOURNAL the exact place of residence of the Treasurer of the ASSOCIATION, that members may know just where to send dues.

F. W. TODD, M.D.

ANSWER:—Henry P. Newman, M.D., 36 Washington Street, Chicago, Ill.

## SOCIETY NEWS.

**American Academy of Railway Surgeons, Meeting of the Publication Committee.**—Pursuant to the call of the President, Dr. C. K. Cole, Helena, Mont., Drs. C. B. Kibler, Corry, Pa.; W. J. Galbraith, Omaha, Neb.; R. Harvey Reed, Columbus, Ohio; C. M. Daniels, Buffalo, N. Y., and Webb J. Kelly, Galion, Ohio, met June 1, at Galion, Ohio, to arrange the preliminary work for the coming session of the American Academy of Railway Surgeons. After considerable discussion, the date of the meeting was set for September 25, 26, and 27. This was thought advisable on account of the previous date conflicting with those of other prominent associations; and

VOL. XXIV.

CHICAGO, JUNE 22, 1895.

No. 25.

## ORIGINAL ARTICLES.

### METHODS OF DIAGNOSIS AND THERAPEUTICS OF DISEASES OF THE STOMACH AND INTESTINES.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY FENTON B. TURCK, M.D.

CHICAGO.

Diagnosis based upon a group of symptoms only is of little significance in determining pathologic conditions, and, therefore, is of no decided value in rational therapeutics. However, symptoms and history must not be ignored. When a group of symptoms present themselves with a history pointing to a gastric disorder, we must depend upon direct examination to complete a diagnosis.

It has always been my custom to make a general physical examination for the purpose of establishing a diagnosis in gastric diseases. I begin with the hair, continue with the eyes, nose, mouth and skin, the general appearance of the body, and especially the contour and configuration of the abdomen. I use boundary lines which connect fixed points: the median line from the interclavicular notch to the symphysis pubis; the parasternal lines (parallel to the median) from the junction of the middle and inner third of the clavicle, to Poupart's ligament; a line connecting the apices of the twelfth ribs; another from the xyphoid appendix to the twelfth rib (on both sides); a transverse line connecting the anterior superior spines of the ilia.

After examining the chest organs, we locate the solid organs of the abdomen—liver and spleen—by the usual methods. Then the size, position and location of the hollow viscera are determined. The usual method of percussion in locating hollow viscera often lead to grave errors, since the stomach may contain food and the transverse colon may be filled with fecal matter, so that the flat percussion may run far below the lower border of the great curvature. If, on the other hand, the stomach is empty and contains gases, and the colon is well dilated and inflated, these conditions may lead to similar errors. The method devised by v. Frerichs and also employed by v. Ziemssen of producing CO<sub>2</sub> with bicarbonate of soda and tartaric acid is now of historic value only. Ewald's method of introducing air through the stomach tube is reliable in cases in which the colon can be outlined definitely. To overcome the difficulty of outlining the colon, Ewald recommends the introduction of water into the colon. This is often impracticable and for obvious reasons can not always be depended upon.

Various instruments have been devised for locating the stomach, for determining its size and outline,

especially that of the greater curvature, and for ascertaining its motility and degree of sensibility on pressure. For determining the degree of pain, especially that found in gastric ulcer, Boas has devised an ingenious method by using what he calls the algescimeter. This consists of a cylinder containing a spring with an indicator graduated in 10 kg. When pressed upon the xyphoid appendix or twelfth dorsal vertebra, it indicates the degree of pressure a person can endure in normal condition. When only from 3½ to 5 kg. of pressure can be endured, it is considered abnormal and arouses suspicion of gastric ulcer.

Einhorn's gastro-diaphane is an electric light which is introduced into the stomach for the purpose of transillumination. It has been found very valuable in determining gastropnoia, simple dilatation and the rare cases of tumors and cicatrices on the anterior wall.

Einhorn also devised an instrument for determining the motility of the stomach. The electric gastrograph, as it is called, is described in the *New York Medical Journal*, September, 1894.

The gastric motor-meter is an apparatus I have devised for determining the contractility and the movements of the stomach. It indicates: 1, the character of the movements—respiratory (passive), or peristaltic (active); 2, the number of movements; 3, the degree of energy of the movements. It consists of a small rubber tube, to one end of which is attached a small oblong rubber bag. When this bag is inflated, it is pear-shaped, and about three inches long with two inches at its greatest diameter. Bags of various sizes may be filled with air or water. The other end of the rubber tube is connected with a Schiel's manometer with water as an indicator. The collapsed bag is introduced into the stomach, inflated with air and connected with the manometer; the rise and fall of the manometer indicate the long respiratory movements and the short peristaltic waves. The small tube of the manometer shows a rise of 30 mm. during ordinary respiration; in deep respiratory movements there is a rise of 200 mm. or more. The peristaltic contractions in health vary from 10 to 15 mm.; in dilatation from 2 to 5 mm.

The fact that respiratory movements affect the pressure on the bag, showing a rise during inspiration and a fall during expiration, is of great significance. From these observations I would conclude that respiratory movements have the most marked effect on the mechanical movements of the stomach contents. The gastric unit is obtained from examinations and observations made on the stomachs of healthy persons. It is found that normal stomachs show 200 to 300 mm. (water) of pressure, produced by the contraction of the stomach and the respiratory movements. From this we can make an exact mathematical formula of the motor power of the stomach.

The contractility and dilatation of the stomach

may also be determined by means of cables of various degrees of flexibility used with the gyromele.<sup>1</sup> The stiff cables, after having been introduced into the stomach and allowed to glide along the great curvature, distend the stomach, while the more flexible cables will not stretch it. The difference between the two indicates the degree of contractility and dilatation. The revolutions of the sponge within the stomach can be readily palpated on the abdominal wall.

The gyromele is not only useful for exploring the stomach, but by attaching the ordinary esophageal ivory bulbs, it can be used to locate strictures anywhere along the esophagus to the cardia. The flexible cable being encased in a rubber tube is less dangerous than the stiff short whalebone formerly used for exploring purposes, which was not at all adequate and always involved danger of puncturing.

We use the gyromele for the purpose of removing adherent material from the walls of the stomach, for microscopic, chemic and bacteriologic examination.

Microscopic examination will reveal epithelial cells of glands, round cells, leucocytes, bacteria of various forms, either in colonies or otherwise. When colonies are found, it shows that there is an active bacterial growth, and a further bacteriologic study is necessary to determine the microorganisms which are present in gastritis.

Chemic examination can be roughly made during the progress of treatment, as, for example, to determine the return of HCl. Dr. Wesener<sup>2</sup> has just finished a line of very interesting experiments in cases of anacidity of the stomach. He has examined the stomach contents of patients after Ewald's test meal and found no HCl. The patients are then asked to return to the clinic with an empty stomach. No HCl being present the stomach is washed out to remove any other acids that may be present. The gyromele is introduced and revolutions are made for five minutes. On chemic analysis in a number of experiments HCl was found to be present as high as .1 per cent. This shows that HCl is secreted on stimulation. I have made use of this fact in establishing a differential diagnosis between functional disturbance and atrophy of the stomach. In simple functional disturbances HCl is produced after the revolutions of the gyromele, while it is not found in atrophy.

After we have determined the size, location and motor power of the stomach and the chemistry of the stomach contents, we make a simple bacteriologic examination. To determine the character of the infection a more extensive and accurate bacteriologic examination is necessary. By simply removing the contents and examining them, we can obtain no exact knowledge of the varieties of bacteria which are characteristic of the disease. The material must be taken from the walls of the stomach. This is done by means of the gyromele. Cultures are then made, preferably by the method of developing microorganisms on the mucous membrane of the stomachs of pigs: 1, this medium approximates a more natural soil for the growth of the microorganisms which are especially found in gastritis; 2, it produces a

more luxuriant growth of colonies in less time; 3, colonies can be preserved *in situ*, the mucous membrane being dried and preserved as parchment.

In carcinoma I have found lactic acid microorganisms to be more prevalent than in any other disease of the stomach. Their presence in carcinoma of the stomach is so constant as to make it of great importance in the early diagnosis of carcinoma of the stomach. (See JOURNAL AMERICAN MEDICAL ASSOCIATION of March, 1895; Turck, on "Early Diagnosis of Carcinoma of the Stomach.")

#### THERAPEUTICS.

Having reviewed the various methods of diagnosis, we will now consider the rational therapeutics that would result from an accurate and complete examination of pathologic conditions.

Lavage of the stomach has been universally used for a number of diseases and is especially indicated in dilatation. In a large percentage of cases, however, where lavage has been practiced, the removal of the stomach contents instead of improving the condition has caused rapid emaciation, on account of the withdrawal of nutritious material, and the dilatation has been increased by the weight of the water. Indications for lavage are limited to selected cases of dilatation.

Massage in the recumbent position has been recommended by both Cseri and Boas, as it empties the stomach and overcomes the objection of withdrawing nutritious material and weighing down the stomach. However, this manipulation does not remove the material adherent to the walls of the stomach, in which are lodged the microorganisms, which form a very important pathologic factor in gastritis. The indications in these cases are:

1. To remove the adherent material.

2. To disinfect as far as possible, or to render the soil unfavorable for the development and growth of microorganisms.

If the stomach has been washed out until the water runs clear, it is observed after the gyromele has been introduced with three to five minutes' revolution that the contents then withdrawn contain thick tenacious masses, in which are found necrosed epithelial cells, cells from the mouth and esophagus, leucocytes and detritus of food swarming with colonies of different varieties of microorganisms. The removal of this irritative material is still further facilitated by the use of soap solution made by dissolving one ounce of green soap in one quart of water. It has also been observed that in cases where there has been anacidity the HCl would reappear after this treatment, and in cases of hyperacidity which might be due to the irritation caused by the microorganisms, this condition was alleviated.

Furthermore, the motor power which had become abnormal, would resume its normal activity. This method with its results was first presented before the International Medical Congress at Rome in 1894.

I now present a method of disinfecting the mucous membrane which I have demonstrated in the laboratory. This method has been used for the past year and has been satisfactorily proved to check the growth of colonies on the mucous membrane. It consists of nebulizing oil of cloves and oil of cinnamon with a simple nebulizer, so that a cloud of pure essential oils is formed. The apparatus I have devised for applying this coating

<sup>1</sup> The uses of the gyromele (revolving sound) was first presented before the International Congress at Rome in 1894, with report of cases. It was also described, with additional cases in the Wiener Med. Woch., Nos. 1 and 2, 1895. It consists of a flexible cable to the end of which is attached a sponge covering a spiral spring which can be removed and changed. The cable passes through a rubber tube and this again is attached to a revolving apparatus for the purpose of producing revolutions of the sponge within the stomach.

<sup>2</sup> Proceedings Illinois State Medical Society, 1895.

to the wall of the stomach consists of a nebulizing bottle, connected with a Wolf bottle; this is in turn connected with a tube, on the side of which is attached a smaller tube, made in one piece with it. The inlet tube extends into the stomach; the outlet or shorter tube extends only to the cardia. The extra bottle prevents the contents of the stomach from entering the nebulizing bottle. The advantage of nebulized oil over aqueous spray is that it remains in contact with the mucous membrane for a longer time. I have also demonstrated experimentally that a thin layer is applied to the whole surface of the stomach. I recently made the following interesting observation: a patient complains of an intolerable sensation of hunger; after the nebulizer has been applied, the sensation disappears and the patient feels very comfortable.

Besides these oils, any substance soluble in glycerin may be used: silver nitrate dissolved in small quantities of water, potassium bichromate (1 per cent. solution can be used with glycerin); a weak solution of formalin. The nebulizer is applied for three minutes. The advantages of oil of cloves and oil of cinnamon in the nebulizer are:

1. It is antiseptic.
2. It prevents the growth of microorganisms. (See experiments in laboratory.)
3. It is analgesic; pain ceases immediately after application, viz., gastralgia.
4. It is a vasomotor stimulant; it assists in removing congestion; a feeling of warmth and well being is experienced by the patient after the application.
5. The introduction of air distends the stomach, and contraction forces the air out through the other tube, so that we have a pneumatic massage.

For cleaning the stomach, I use an apparatus which consists of a double tube; a small short tube with a perforated ball at the end to be introduced into the stomach; a larger tube for the immediate return of the water introduced. The water is forced through the small short tube under pressure and returns through the large tube. This procedure will remove material from the walls, especially if soap is used. The apparatus possesses a great advantage over lavage, as it will simply remove loose material in the lumen.

Among other advantages of this process of cleansing the stomach may be mentioned: in cases of dilatation, the large quantity of water which is necessary to wash out the stomach only aggravates the already prolapsed condition and distension of the stomach. To overcome this objection, Fleiner recommends lavage in the recumbent position. In using the apparatus I have described, the water returns immediately through the large tube, so that it is impossible to overload or distend the stomach. Not only does this apparatus cleanse the stomach, but it also acts as a needle-douche, and as such is a vasomotor stimulant. It has been used with remarkable results for the last year in cases of pronounced gastroparesis and dilatation, restoring the latent muscle and sluggish vessels to their normal condition.

Before this treatment, soap and water or one-half of 1 per cent. of formalin, or thymol, or resorcin, or oil of cloves is introduced through a syringe with the gyromele. As before stated, liquid soap is made by dissolving an ounce of green soap in one quart of water and is especially valuable in removing irritative material from the walls of the stomach, as well

as cleaning the mucous membrane and neutralizing acids.

Lysol, 30 minims, to 1 liter of water with the liquid soap is a valuable antiseptic solution. It is useless, however, to apply antiseptics before the stomach has been thoroughly cleansed.

#### GENERAL THERAPEUTICS.

Congestion of the stomach and abdominal viscera is shown by cold hands and feet and the peculiar color of the fingers and lips. To distribute the blood over the body and remove the contraction of the arterioles, the following bath (described in *Wiener Med. Wochenschr.*, No. 2, 1895) is used: the patient is placed in a common salt bath at 100 degrees F. and requested to lie quiet. The temperature is raised 110 to 112 degrees F., in some cases to 116 degrees F., until the whole surface of the body has turned red. The patient is then removed from the bath and massaged all over the body with a cake of ice. This stimulates the vasomotor nerves and increases the heart's action. A stream of ice water containing a little ammonia is directed to the body of the patient. A large horse syringe or pump is used in applying the stream. The procedure is similar to a Scotch douche.

#### ADVANTAGES OF THE BATH.

1. It increases the metabolism of the body, producing general activity.
2. It effects the removal of toxins.
3. It promotes the supply of fresh arterial blood to the tissues.

The stimulation lasts from six to twenty-four hours, according to the case. General improvement ensues immediately, as the bath has no weakening effect.

A bath is given every day during the first week; then three times a week until the general condition of the body has improved. Counter-indication: mitral regurgitation without compensation and fatty degeneration of the heart.

#### TREATMENT OF THE INTESTINES.

For the purpose of lessening putrefaction in the intestines, a pill is made, containing oil of cloves and oil of cinnamon, and in some cases ox-gall; this is coated with several layers of shellac and betol. The coating is not dissolved in the stomach and the pill passes into the intestines where it is set free. Remarkable clinical results have been obtained in some obstinate cases of diarrhea by the use of these pills.

Cases of dilated sigmoid and atony of the lower bowel and severe cases of constipation have been overcome through the use of the gyromele with revolution. Where there is marked congestion of the colon, atony of the colon, and retention of fecal matter, I have introduced ice water through a soft rubber tube. The patient lies with hips elevated; the ice water is introduced and then massaged out through the tube after it has been disconnected from the reservoir which is placed five feet above the patient.

#### ADVANTAGES OF USING ICE WATER.

1. It stimulates the vessels; and
  2. Increases the muscular action of the colon.
- Lavage of the colon with warm water simply washes out the mucus, which should be retained in certain cases for the purpose of lubrication. Its removal aggravates the symptoms of constipation.

Two quarts of ice water are generally used to which in some cases tannic acid may added; also lysol, one ounce to one quart of water; liquid soap; inspissated ox-gall to one quart of water.

Constipation is also much improved by eating bran gems three times a day with meals. Common bran from the feed store is used in making these.

#### ADVANTAGES OF BRAN GEMS.

1. They mix with the food and assist in the churning process.

2. They furnish material for stimulation to the whole intestinal tract.

3. They do not furnish a nutrient medium for the growth of microorganisms.

Boas recommends the use of two teaspoonfuls of milk sugar at night to overcome constipation. This, however, has been found inadequate. Treatment by dietetics, the use of bran lavage of the colon with ice water, the use of the gyromele as described, with the addition of faradization as recommended by Ewald, have given very satisfactory results.

#### MECHANICAL THERAPEUTICS.

In many cases of gastric disease, the abdominal walls are relaxed, so that they allow the protrusion of the abdominal organs, presenting the appearance known as Glenard's disease. The common abdominal belt is not sufficient to hold up the abdominal wall, as it simply presses the organs backward. I therefore utilize the usual web abdominal belt, to which I have affixed lifting straps. The lower strap is drawn first. It is fixed just above the pubis, passes through loops on each side and runs upward and backward and is buckled to the support at the back. A second strap is attached above this and also brought to the support at the back. This elevates the viscera and keeps them in place. However, this is not sufficient, as it will not cause hyperplasia of the abdominal muscles which is necessary to hold up the viscera. For the purpose of producing hyperplasia I use Gaertner's ergostat. This apparatus is something like a grinding-stone. The patient turns a wheel with friction brake, which is weighted to suit different cases. I have devised a method of using the abdominal muscles by extending the arms and legs perfectly straight, thus throwing the work mostly on the trunk and giving exercise to the abdominal muscles. Deep breathing exercises, arm extension, backward bending, side-twisting are the movements performed. During all the exercises the legs must remain extended, so as to throw the work on the trunk as much as possible. The best physiologic effect is obtained by exercising slowly. Respiratory exercises are the best for the stomach, since they produce stomach movements.

#### DISCUSSION.

DR. STOCKTON—I am not willing to allow this very interesting paper to pass without discussion. The Doctor has taken up so many points that he has not been able to give to some of them the attention which he would like to give and which he will undoubtedly complete in further contributions. He has suggested a great variety of thoughts. The contributions that he has made to the treatment of gastric diseases are certainly very ingenious and very interesting. He has spoken of the function of the instrument which he calls the gyromele which seems like a very interesting instrument. The Doctor speaks of the use of that in differentiating between the functional acidity and gastric disturbance. I can not quite agree with him as to that point. We have various degrees of acidity. There are many cases of functional acidity, without, to my mind, demonstrable lesion of the mucous membrane where even marked irritation

by electrical currents, or other local stimulants in the form of drugs, seem not to produce local symptoms. Occasionally we do find an acid secretion. As to the limitation of lavage, there can be no doubt that lavage, like every other new procedure, has spread widely into popular use for obvious reasons, but has been overdone. It is used where it is quite improper, and without any depth of purpose in view. I congratulate the Doctor upon calling attention to the uselessness of lavage in many conditions, and in cutting down its use to merely emptying the stomach in a therapeutic sense. Finally, may I ask him to explain a little more definitely about the coating of the pills to which he referred, so that we can know exactly how it can be obtained, or how we can get this coating. The ordinary pills which pass the stomach untouched are very prone to pass the intestines untouched.

DR. TURCK—The statements that this revolving apparatus does relieve functional disturbance and stimulates the formation of hydrochloric acid were quite as surprising to me as they are to the Doctor now. This work was accomplished by Dr. Wesener, who is with me in the clinic work, and a large number of cases were examined. We found by all the other means that we could not in any way produce any hydrochloric acid. The introduction of drugs is not sufficient; you can give any amount of hydrochloric acid, nux vomica or faradization, but there would be no amount whatever found in the stomach. The introduction of the revolving apparatus for five minutes would start up a circulation, and at once stimulate all the glandular elements of the organ, because you reach the whole of the stomach. I have been able to apply materials in the entire organ in that manner, and demonstrate it upon animals. As to lavage, about four years ago I used to think that lavage was a great thing, but we would find that some of the cases became thinner under its use. In fact, many of our cases would become rapidly emaciated. At first we thought it was because of the loss of the food which was washed away, and many would come with an empty stomach, and we washed out the secretions. The simple washing out of the stomach is not sufficient in gastric disturbances. In cases of dilatation the removal of the irritating material is quite useful. But it seems apparent that the secretions which are removed by the use of lavage are essential to the system, and that their abstraction results in nutritive loss. As to the pills, Dr. Rode, of Chicago, has made those pills. Several coats of shellac and betol were found to be necessary. The pills were dipped into the fluid, and then taken out and allowed to dry, and then this was repeated over and over again. These pills were found to pass through the stomach into the intestine, without being absorbed in the stomach and contents set free in the intestine.

NOTE.—All the apparatus mentioned in this article can be had of Tieman & Co., New York; Hausman & Dunn, Sharp & Smith, or Truax, Greene & Co., Chicago.

## THE DIFFERENTIAL DIAGNOSIS OF CHOLELITHIASIS.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY GEORGE W. WEBSTER, M.D.

PROFESSOR OF PHYSICAL DIAGNOSIS, NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, CHICAGO.

*General Statement.*—Gall stones were observed by Johann Kentman in 1565. They occur at all ages, having been observed in the newborn infant. Ten per cent. of all adult males,<sup>1</sup> 25 per cent. of all adult females<sup>2</sup> and 36 per cent. of the insane<sup>3</sup> have gall stones. Schroeder of the Strassburg Hospital, says they are found in 4.4 per cent. of all males and in 20.6 of all females, especially if they have borne children. The number varies from a single stone to over eight thousand.<sup>4</sup> Symptoms are observed in 1 per cent. of those having gall stones. As the surgery of the gall tracts is brilliantly successful and inasmuch as solution of the stones is an illusion, and removal by medicines is seldom successful, an early and correct diagnosis is important, that we may turn them over to a surgeon whom they should consult, in

order that they may have a chance for recovery. Send them to a surgical clinic and not to Carlsbad.

*Diagnosis.*—In the differential diagnosis of cholelithiasis it will facilitate our thinking about the matter if we divide the cases into two classes, placing in the first class those in which there is stone in the cystic duct, or in the gall bladder, describing the signs and symptoms and considering also those affections with which it is liable to be confused.

In the second class we place all those cases of stone in the common duct. The latter are always accompanied by more or less jaundice, while in the former, for very obvious reasons, jaundice is absent. We should not forget, however, that in a given case it may, in the early stages, belong to the first class, while the stone is still in the cystic duct, and that it may subsequently pass on into the common duct, and give rise to all the characteristic phenomena of obstruction at that point.

As already stated, the fact that 10 per cent. of all males and 25 per cent. of all females have gall stones, while only 1 per cent. of all these have symptoms, makes it evident that we are to concern ourselves only with those cases which manifest symptoms of stone in the gall bladder or in the cystic duct. The diagnosis is sometimes easy and at other times it is exceedingly difficult. The most characteristic symptom is the colic which consists of an acute, severe pain coming on a few hours after a meal, at the time when the food is passing through the duodenum. It is usually felt in the right hypochondrium or in the epigastric region, is commonly sudden in onset, and varies from a feeling of uneasiness and discomfort, to one of such extreme agony that it becomes unbearable and convulsions may occur.

The duration and intensity of the attack are varied by the size and situation of the stone, or stones, the age of the individual, the posture of the patient, lying on the belly often relieving the pain, the course of the stone whether dropping back into gall bladder or passing on into the common duct, and lastly, intensity of the nausea and vomiting. Probably the extreme relaxation allows the stone to fall back, pass on, or permits the bile to flow by or else relaxes the spasm of the muscles of the duct. The pain may last from a few minutes to a week. Southworth says<sup>5</sup> that histology has demonstrated that in youth the muscular fibers are abundant in the walls of the duct, while in old age they have either atrophied or disappeared. This is denied by Strumpell. This would explain the variation in intensity and duration of the pain which is probably caused by the spasmodic contraction of the muscular fibers upon the passing or impacted stone.

The accompanying symptoms are chills, fever as high as 104 degrees F., profuse sweats, but without distinct regular periodicity. The pulse is frequent, small, soft, the face pale, bathed in a profuse sweat, there may be a condition of collapse and reflex cramps may occur in the legs, arms, etc.

*Physical Examination.*—It may be laid down as a general proposition that dilatation of the gall bladder is common and that atrophy of the gall bladder is uncommon where there is any obstruction of the cystic duct from stone in the gall bladder. On the other hand, atrophy is the rule where there is movable stone in the common duct. The gall bladder may vary from the normal size to that of a large

tumor reaching to the pelvis. When there is a palpable tumor it will be found to descend with inspiration, is continuous with the liver, describes the arc of a circle, the center of which is beneath the right lobe of the liver,<sup>6</sup> is not as freely movable as a movable kidney. In rare cases, the rubbing of the stones in the gall bladder may be felt by the palpating finger. When in addition to the tumor, the kidney may also be palpated this serves to distinguish them. In rare cases the grating sound may be heard upon auscultation, and still more rarely, a friction fremitus from a localized peritonitis may be elicited by the same method of examination. During the attacks there is tenderness over the region of the gall bladder. When, in addition to the foregoing, the stones are found in the feces, it amounts to an absolute demonstration. The occurrence of jaundice makes it almost equally certain. It is to be borne in mind, however, that gall stones may remain in the bowels for many days, and also what is far more important, that not finding them in the stools is only negative evidence, as it has been shown experimentally<sup>7</sup> that when gall stones are swallowed, they may be dissolved in the alimentary canal and do not reappear in the feces. Exploratory puncture needs to be mentioned only to be condemned as criminal.

The mode of termination of an attack may be either by the falling of the stone back into the gall bladder, it may pass on into the intestines, or it may become impacted in the common duct. The intervals between the attacks vary from a few days to many years. A stone in the gall bladder may be passed and, no others forming, there is no recurrence of the colic. On the other hand, when there is a movable stone in the common duct one of the characteristic evidences is frequent recurrence, perhaps every few days. Lastly, with stone in the gall bladder or in the cystic duct, there is an entire absence of the characteristic signs and symptoms of stone in the common duct. It will readily be seen that, while the diagnosis is easy in the typical case, it might readily be confused with lead colic, malaria, renal colic, peritonitis or gastralgia. The following points ought to serve in distinguishing them:

*Lead Colic.*—This may commonly be easily differentiated, because, in addition to the colic, there is nearly always some of the other manifestations of plumbism. We should consider the occupation, water supply, food, cosmetics, etc. Among the other evidences are blue lines along the gums, lead may be found in the urine after the administration of the iodid of potassium, there may be dropped wrist and obstinate constipation. In addition to these more common evidences there is anemia, there may be multiple neuritis, with sensory and motor derangements, and cardio-vascular-renal changes are common.

*Malaria.*—The chills and fever followed by profuse sweats which occur in cholangitis or cholecystitis may be differentiated by bearing in mind that in malaria the chills are distinctly periodical, the spleen is enlarged, the complexion is sometimes characteristic and, lastly, the plasmodium of Laveran will be found in the blood.

*Renal Colic.*—In renal colic the pain is more likely to start in the lumbar region, extend forward, thence downward along the inside of the thigh and also to the testicle in the male, causing its retraction. There will be present vesical tenesmus, tenderness over the kidney, blood and pus in the urine, absence of bile

in it, and the feces will be normal in color. If the kidney be movable and enlarged it may be grasped between the two hands and will not descend with inspiration, is freely movable and may be replaced in its normal position, and the colon usually lies in front of it. It goes without saying that it is only in disease of the right kidney that any confusion can arise. Tumor in the region of the gall bladder may be due to carcinoma of the head of the pancreas, echinococcus cyst, fecal impaction, renal tumor or movable kidney.

*Peritonitis.*—While there is a remote possibility of peritonitis and hepatic colic being confounded, yet the association of the former with nephritis, typhoid fever, dysentery, tuberculosis, appendicitis, infectious diseases and trauma, the hard, small, tense pulse, drawn face, shallow thoracic respiration, tympanitis, vomiting, etc., should leave no doubt in the mind as to the true nature of the affection.

*Gastralgia.*—Pain in the stomach is due to irritation of the sensory fibers of the vagus, either in its terminal filaments or nucleus, or in reflexion from higher centers. Thus the causes may be numerous, the manifestation uniform. The attacks of pain may closely simulate an attack of gall stone colic. Indeed, I have no doubt that many of the cases diagnosed as gastralgia are hepatic colic. The following points should be borne in mind: that not uncommon class of cases where the gastric crises are among the earliest manifestations of tabes as first described by Charcot. The other evidences of this disease of the cord would enable us to make a correct diagnosis. Then there are the hysterical gastralgias where the detection of the hysteria enables us to recognize the true nature of the affection. The gastralgia of neurasthenia will be associated with other evidences of the neurasthenic condition. In all the foregoing, there is no fever, no palpable tumor, the onset of pain has no reference to food or time of day, there is no change in the taste in the mouth, no gall stones are found in the feces, and lastly, they never end in an attack of jaundice with the characteristic changes in skin, pulse, urine, feces, blood, etc.

It seems probable that we are not yet in a position to be dogmatic in regard to the question whether a cholangitis or a cholecystitis is present or not, as we may have fever, chills and sweat without any lesion of the mucous membrane, while on the other hand, empyema of the gall bladder may exist without chill, fever or sweat.<sup>8</sup>

*Stone in the Common Duct.*—The early diagnosis of stone in the common duct is of the utmost importance, as the operative procedures instituted for its relief are more difficult and dangerous than for stone in the cystic duct or gall bladder, and at the same time the indications for removal are more imperative. In most cases, the diagnosis ought to be reasonably easy if the following evidence is carefully considered:

*History.*—Remember the age, sex, and if a female whether she has borne children. A very important point is the history of a previous attack of jaundice, even though many years have elapsed. Also whether it has been preceded by attacks of colic, unaccompanied by jaundice, and perhaps diagnosed as gastralgia.

*Jaundice.*—As all jaundice is obstructive,<sup>9</sup> it must follow that this is one of the most constant signs of stone in the common duct. Immediately after an attack of colic the jaundice becomes intense, while

in the intervals between the attacks it fades but does not disappear entirely so long as the stone remains in the duct. A varying degree of jaundice which does not disappear entirely between the attacks is characteristic of a movable stone in the common duct.

*Colic.*—The attacks of pain are similar in character to those already described. They may be slight, vague, short, or intense and long. When there is a movable stone in the common duct, and it is too large to be passed and where the duct is dilated sufficiently to allow the stone to move freely in the duct, the attacks are usually frequent, occurring every few days, are not often very severe and nearly always relieved by lying on the belly. On the other hand, with stone in the cystic duct, the intervals between the attacks may be from a few days to many years. The attacks are usually accompanied by chills, fever and profuse sweat.

*Urine.*—During the attack of colic the urine contains an abundance of bile, while in the intervals it is diminished but does not disappear entirely. Biliary poisoning or cholemia ultimately causes some degeneration in the hepatic cells. Poisonous products are not rendered innocuous in the liver. All these products irritate the kidneys and renal inadequacy results. There may be a slight amount of albumin in the urine, the latter being lessened in amount. The urea is diminished on account of the interference with the function of the liver, the total solids are much less than normal, and this faulty lessened elimination of waste products is probably the cause of the melancholia, while the renal inadequacy is one of the great dangers in severe, long-continued jaundice from any cause. So long as the poisons are eliminated by the kidneys the urine is poisonous and may cause convulsions in animals, but if the kidneys become inadequate then the patient may be poisoned. Jaundice urine is convulsive and not narcotic.<sup>10</sup> This liver inadequacy also explains why it is that in some of these cases, some time before the fatal termination, the jaundice begins to fade, this leading to the fallacious hope that the patient is improving. Instead of being a beacon of hope it is often a signal of grave danger.

*Stools.*—During, and frequently long after the attacks, the bowels are obstinately constipated and the stools are clay-colored. In the intervals between the attacks the feces may be coated with a darker layer and the breaks and fissures may be colored, showing that some bile is reaching the duodenum.

*Circulatory System.*—The pulse is slow and infrequent, often not over 40 per minute, the blood pressure is low and septic endocarditis may occur. The blood shows a fragmentation and destruction of the red corpuscles and the hemoglobin is diminished.

*Digestive System.*—The appetite is poor, tongue coated, bad taste in the mouth and the rate of diminution in body weight is proportioned to the degree of obstruction. In addition to the foregoing there is intense itching of the skin, tendency to hemorrhage, melancholia, etc.

#### PHYSICAL EXAMINATION OF THE LIVER REGION.

It may be laid down as a general rule that a continuous obstruction of the common duct, from any cause, leads ultimately to dilatation of all the biliary passages, including the gall bladder. This is seen in a marked degree in cases of compression from cancer

of the head of the pancreas, malignant disease of the duodenum involving the duodenal end of the common duct. Nevertheless, it may be asserted with equal dogmatism that in cases of movable stone in the common duct, there is ultimately atrophy of the gall bladder, and this atrophy of the gall bladder is one of the most characteristic signs of movable stone in the common duct. Not only this, but it gives indisputable evidence of the folly of connecting an atrophied gall bladder with the duodenum.

The statement is made by Frerichs,<sup>11</sup> that the gall bladder is dilated, and yet he tells us that he observed that later in the disease it "gradually lost its tenderness and distension and caused but little inconvenience."

The reason for the atrophy of the gall bladder is probably the following: with the patient in the upright position and with a movable stone in the common duct, it is most easily accommodated, naturally lies at the mouth of the cystic duct and thus by its action as a ball valve, prevents the bile from reaching the gall bladder. The bile has a specific gravity of 1010,<sup>12</sup> while gall stones, especially when composed largely of pigment and calcareous salts, etc., may have a specific gravity as high as 1966.<sup>13</sup> If the patient lies on the belly, the stone, sometimes from the force of gravity alone, falls back into the wider portion of the tube, the flow of bile is less obstructed and relief is obtained. On the other hand, patients tell us that they hope they will get very sick, as they will then get relief more quickly. Nausea and its accompanying relaxation allows the bile to pass the obstruction. The change in the urine, feces, skin, pulse, etc., have already been described.

Not only is the course as described, important from a diagnostic standpoint, but it is of far greater importance in indicating methods of operation. This paper is intended to discuss diagnosis only, but as a medical man I desire to enter my earnest protest against simply connecting a gall bladder, atrophied from obstruction, with the duodenum and then not removing the stone from the duct. It does not do away with the ball valve action of the stone, increases the liability to malignant disease<sup>14</sup> and is of little value to the patient.

Any one of the following may be mistaken for stone in the common duct: catarrhal jaundice, cancer of the pancreas, cancer of the gall bladder or ducts, cancer of the liver, malaria, disease of the heart, tuberculosis of the liver.

*Malaria* has already been considered.

*Catarrhal Jaundice* follows or accompanies gastric disturbances. There is absence of chills, temperature, colic, extensive emaciation and the jaundice is of a mild unvarying type.

*Cardiac Disease* which causes such extensive hepatic engorgement, thus favoring the accumulation of mucus in the tubes, may give rise to jaundice, but it is apt to be mild in degree and the evidences of cardiac disease could not possibly be overlooked by any careful diagnostician.

*Cancer of the Liver.*—Remember, that cancer of the liver is nearly always secondary, that the liver is usually enlarged, that there may be irregular, dense, firm, hard nodules, rapid emaciation, cancerous cachexia, ascites, malignant disease elsewhere, jaundice of gradually increasing intensity, or else absent entirely. The gall bladder will be greatly distended if the growth involve the common duct.

*Cancer of the Head of the Pancreas.*—This disease is often diagnosed as gall stones. In perhaps the majority of cases, a correct clinical diagnosis is impossible. To decide between an immovable stone and cancer of the head of the pancreas is rarely possible. Both may cause jaundice of an unvarying intensity, or, if any variation, then a gradually increasing degree. When the pancreas is affected and there is pressure upon the common duct the jaundice is constant. In cancer of the caput there may be pain of a lancinating character, glycosuria, intestinal indigestion, fat in the stools, cancerous cachexia, ascites if the veins be compressed. The onset of the jaundice is gradual, not sudden and not preceded nor accompanied by colic, and the gall bladder will usually be found to be dilated.

*Cancer of the Gall Bladder or Ducts.*—Unlike malignant diseases of the liver, cancer of the ducts and bladder is commonly primary. When we remember that Musser has shown<sup>15</sup> that 91 to 95 per cent. of all cases of cancer in this locality are accompanied by gall stones, and that the latter probably bear an etiologic relation to the former, it will be conceded that the clinical picture will change, depending on whether the stone or the new growth is the predominant factor in the case. It is probably seldom that a correct clinical diagnosis is made.

The necessity of an early correct diagnosis is perhaps best indicated and emphasized by the dangers of delay. Perhaps the greatest and most important of these is renal inadequacy, as already pointed out. Then we must remember the possibility of organic change in the liver itself, the increased tendency to malignant disease and the danger of cholemia in an attack of which the patient may die. Even though the patient do not succumb to an attack of cholemia, the heart may become so weakened and its muscle so degenerated, the blood pressure so low, and the tendency to hemorrhage so much augmented that it increases the danger of operation and the probability of death during or soon after it, either from renal or hepatic inadequacy. Suppurative cholangitis with or without perforation is not a remote danger, and either may lead to a fatal termination. When a stone has been diagnosed in the common duct and there is progressive emaciation and cholemia, the patient should be operated upon without delay.

In only one of the cases upon which this paper is based, was an attempt made to determine this point. The patient was my own brother and the case was one of multiple stone in the common duct. There were chills, sweats and a temperature of 102 degrees F. He was operated upon by Dr. Christian Feuger of Chicago, and at his suggestion, Dr. Stanley P. Black made cultures upon agar-agar and gelatin, both from the bile as it flowed from the wound, and also from the scrapings from the surface of the stones. These cultures were negative.

#### DISCUSSION.

DR. MUSSER, Philadelphia.—There are many thoughts which arise in connection with a paper of this character, and there are a few, especially, dwelt upon by the report in Dr. Webster's paper which to me are of striking interest, and I think should be emphasized. From very considerable experience in connection with cholelithiasis, I am sure that we

can not rely as definitely upon age as an element in the diagnosis as the text-books would lead us to infer. We have been taught that gall stones, prior to 30 years of age, were extremely rare, at least the symptoms which lead us to believe they are present were of rare occurrence. My ideas in regard to this have been changed, and I am sure that as early as the fifteenth year gall stones may be formed and may give rise to symptoms. This was very much emphasized by a case which came under my notice during the winter; a man 24 years of age, of the bilious type, had obstruction of the common duct. The diagnosis was made without much difficulty, and after being under observation for a short time it was found necessary, because of the rapid destruction of the blood, to employ surgical measures. Some 160 gall stones were removed. The interesting point about it was that the very attacks from which he suffered at the time that we could diagnosticate biliary obstruction, he had suffered from since the time he was 13 years of age, and I am quite sure that these attacks of pain in the epigastrium were due to the presence of gallstones. There were found such an enormous number of stones that it was almost positive that a long term of years must have elapsed during their development. Many of the stones were large, exhibiting a number of layers, which must have required many years in their formation. Again, in regard to this very symptom of pain, I am sure that we have cases of biliary obstruction without the occurrence of much pain. Pain is a symptom which is present in a large majority of instances, but it may come on suddenly, and at stated intervals, and still be due to gall stones. In a recent case the pain was not only a remittent factor, but there was scarcely any distress in the region of the liver. Every two or three weeks, however, there would be an attack of distress, with vomiting, clearing off in a short time, with the other evidences of cholelithiasis. In the differential diagnosis, the question of gastralgia was touched upon. I am beginning to be suspicious of gastralgia as a disease, except in connection with neurasthenia, and organic nervous disease, as locomotor ataxia and save, too, in connection with organic disease of the stomach. I am inclined to think that a large majority of the cases that are called gastralgia are due to gall stones. I am satisfied that if the pain is severe, and if the patient is debilitated or prostrated on account of the pain, that an exploratory operation is certainly warranted, in order to determine absolutely the presence or absence of cholelithiasis. In many cases which had been treated, just as this young man I refer to had been treated, for gastralgia, the trouble has turned out to be gall stones. Barring the limitations I have given, gastralgia is extremely rare. I should like to have heard the reader laying down some of the diagnostic indications by which we could be guided to resort to operative measures. He did refer incidentally to renal indication and the danger of development of polemia. I am guided very much by the examination of the blood. The bile destroys the red blood corpuscles, and after the destruction falls below 3,000,000 it is surprising to find how rapidly this takes place; it is, indeed, not only surprising but shocking. A case which I had under observation fell to 2,500,000, and suddenly I found the blood reduced to 1,800,000, and he went into profound polemia, or the comatose state which accompanies profound anemia and death ensued, whereas if I had resorted to operation early the patient's life would probably have been saved. Watching the blood, therefore, is an indication. I do not feel that in a case of gall stone you should at once resort to operation. You ought to hold your hand firmly on the case, observing the urine, and all the other conditions, observing all the danger signals, and when these are out do not hesitate to operate.

One word further: many diseases have been confounded with gall stones, and I think Dr. Orr of London wrote a paper on these affections. I would refer to a case of pneumonia I was asked to see. The patient was being treated, however, for gall stones. The man had a very intense and severe diaphragmatic pleurisy; he had ascites, as often occurs in pneumonia; there was vomiting, and many other symptoms of the hepatic colic, and the physician in attendance felt quite sure that he was treating a case of hepatic colic. One of the very important symptoms, and a symptom I always inquire into and believe to be present, is the occurrence of fever. This has been so extensively treated in papers recently that it is not necessary to refer to it again, that is, to that form of hepatic intermittent fever, except to say that it is a common form, very frequently attending gall stones, and may lead to confusion with other affections.

Dr. TURCK, Chicago—It is to be regretted that there is not more time for the discussion of this paper. There are two

points of importance in differential diagnosis between gall stones of the cystic duct, of the gall bladder and of the common bile duct. The differential diagnosis must be made, as it is of great importance. In the bile stones of the common duct, in which there is a sacculi formed behind the opening, we can not consider anything else in a case like that but an operative procedure at once, because we have seen the disastrous effects from retention of poisons, the irritation of the vessels, etc. What is the temperature due to? There has been a great controversy waged between two schools, the German and the French, upon this point, the German holding that it is bacteriologic in its nature, and the French claiming that there are no germs connected with it. Recent experimentation has thrown the balance in favor of the French school, because the bacteriologic examination of the gallstones of the bile, and of the material from the walls has revealed negative results. As to the differential diagnosis between bile stones in the cystic duct and in the gall bladder, and the differential diagnosis between those in the gall duct, a little remembrance of anatomy is required as to the manner in which the cystic duct branches off, running to the gall bladder. There is atrophy in case of obstruction of the bile duct, of the gall bladder, and there is dilatation of the gall bladder in cases of gall stone of the cystic duct, because in case of gall stone of the cystic duct we have an increased secretion of fluid and dilatation occurs. In the other case there is a loss of use of the gall bladder and atrophy results. We are also aided in this differential diagnosis by the examination of the blood, of the urine, by the physical examination, and a careful analysis of the symptoms of the case.

Dr. WEBSTER—The point referred to by Dr. Turck of Chicago, in regard to the etiology of these cases is very important, and yet in my paper I simply made this note, and did not really intend that it should go into discussion. I appreciated the importance of it, but did not want to take it up, as I desired to confine myself as far as possible to the diagnosis and not to the etiology. Dr. Musser regretted that I did not go more thoroughly into the question of indications for operation. The statements which I made were that the indications for a correct diagnosis were those that indicated operation. If there is gradual emaciation, with the evidence of stone in the common duct, it is an absolute indication for operation. I referred also to the examination of the blood. The careful examination of the blood, estimation of the hemoglobin and number of corpuscles from day to day is a better fact in determining the patient's condition than clinical evidence, but where you can not do this you must rely upon the clinical evidence that the patient is losing in weight. I wish to emphasize again, not only the state of the blood, but the condition of the heart. We have degeneration of the heart muscle; renal injection; liver injection, and I think these last two points especially have not been understood by the profession as they should be, and that whenever we begin to get renal and hepatic injection, these are signs of great danger and absolute indications for operation.

## TREATMENT OF ASIATIC CHOLERA.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY ELMER LEE, A.M., M.D., PH.B.

CHICAGO.

Spasmodic cholera—called also malignant, epidemic, Asiatic, Indian, blue, and pestilential cholera—is generally epidemic, though not contagious. The first symptoms are generally experienced during the night, sometimes beginning with a light general uneasiness and moderate diarrhea; at other times the symptoms come on violently and follow each other rapidly. In fatal cases death usually occurs at some period between six and twenty-four hours; in a few fatal cases the patient lingers two or three days. The ordinary course of symptoms are more or less diarrhea; the discharges at first feculent, but soon presenting the appearance of rice-water or gruel; there are flying pains, or sense of coldness in the abdomen, as if purgative medicine were about to operate; the countenance is pale; there is nausea, vomiting, prostration of muscular power, and nerv-

ous agitation; cramps in the legs, arms, loins and abdominal muscles, more or less severe; small, weak pulse, intense thirst, and urgent desire for cold water; in most cases cold, clammy skin; all these symptoms may appear successively or almost simultaneously. In some cases the premonitory symptoms exist for eight or ten days; and sometimes the patient is prostrated at once. When the disease comes on suddenly the cramps usually begin in the fingers and toes, rapidly extending to the trunk; the eyes are sunken and surrounded by a dark circle; there is vomiting and purging of white matters mixed with flocculi; the features are sharp and contracted; the expression of the countenance wild and confused. The face, extremities, and often the whole surface of the body manifest a varying intensity of a leaden, bluish or purplish hue; the extremities shrunken, the nails blue, the pulse thready or wholly imperceptible at the wrist, arm, axilla, temple or neck; there is great restlessness, incessant jactitation, severe pain in the epigastrium, loud moaning or groaning, difficult and oppressed breathing; difficult inspiration, with short and convulsive expiration; voice hoarse, whispering, or nearly suppressed and plaintive; the tongue is white, cold and flabby, and the external temperature often sinks below 80 degrees; convulsions recur at short intervals, or a constant tremor exists. The secretions of bile, saliva, tears and urine are entirely suppressed, and a cadaverous odor exhales from the body. The patient retains his faculties to the last.

Some of the symptoms may be disproportionately severe, or may be entirely absent. Those usually regarded as pathognomonic are: watery dejections, blue appearance of the countenance or surface, thirst, coldness of the tongue, and pulselessness at the wrist.

The foregoing description of the symptoms of cholera is indicative of the nature of the disease calling for human aid. The time in which to treat the patient sick with cholera is exceedingly limited. What is to be done must be executed with rapidity. There is not a moment to lose between the time when the patient is first seen and the accomplishment of severely practical efforts. Many wise theories may be promulgated, but there are few practical measures that will avail against Asiatic cholera. The experiences during the cholera epidemic of 1892 in Europe, both in Russia and Germany, produced in me a profound conviction that, for the most part, remedial agencies that have been used are of questionable utility. Nearly every prominent remedy proposed and tried has been found to end in greater or less disappointment. Years ago, great reliance was placed upon the far-famed "mild chlorid of mercury." Twenty and ten years ago this remedy was given in large doses. Three years ago, during the latest epidemic, small doses prevailed. Next to this, the synthetic drug salol, the product of the laboratory of the Imperial Institute of Experimental Medicine in St. Petersburg, was the most widely used and the most favorably received. Professor Nenski, the originator of salol, personally informed me that the value of the drug could not be seriously recommended as of much importance, but that it perhaps answered the requirements as far as any drug could answer, in the hands of his colleagues. Widely circulated and various reports, enthusiastically commending and moderately commending this

remedy were received by the Professor in St. Petersburg, but he himself was silent as to its efficacy. The far-famed and seemingly unmatched drug, quinin, has been used, and has been held as a dazzling gem before the eyes of the profession by some of our best men, who believe that cholera is analogous to malarial disorders, and consequently the medicine which occupies the position of keystone in the arch, for malarial treatment, is a remedy suitable to contend with the rapid and desperate symptoms of Asiatic cholera. Quinin has a stout advocate in our own country, in the person of a well-known professor in one of the Ohio medical colleges. It was not used, to my knowledge, in the treatment of cholera during the last epidemic in Europe.

A remedy was brought to Hamburg during the latter part of the epidemic of 1892 by the representative of an English syndicate, who posed as a chemist, not a physician. His remedy was a preparation of iodine, to be administered through the mouth. He called the medicine a periodate, and made some experiments upon patients in one of the cholera hospitals in Hamburg. His remedy, however, was not favorably entertained by the medical authorities in charge of the cholera patients, and whatever claims were reported came through the interest of a friendly correspondent of one of the Hamburg weekly secular papers. To show how misleading some of our supposedly authentic information often is, it is only necessary for me to refer to the report given in the "Year Book of Medical Progress," published in Philadelphia. Of all the progress made, of all the combined investigations during the entire epidemic of cholera throughout Europe in 1892, and there was an immense amount of original investigation and great effort made to discover a remedy, the curious spectacle in the Year Book, which alone refers to the remedies brought by an agent of a syndicate from London to Hamburg, at the closing of the epidemic of cholera, shows that there are some things in our profoundest medical publications that are to be taken *cum grano salis*. Uretin was extensively used hypodermically for its alleged influence upon the secretions of the kidneys, upon the ground that the kidneys were to be aided by irritating them to greater functional activity to eliminate morbid elements through the urine. The result of many investigations recorded in Russian practice show that this drug is not to be commended. Digitalis was used, supposedly to benefit a weak heart. This remedy, if at all useful, could be little more than palliative. The use of acidulated water was extensively employed in different hospitals in Europe as a drink, but not prescribed as a remedy. The water was acidulated with HCl and H<sub>2</sub>SO<sub>4</sub>. Subcutaneous injections of salt water were made. The proportion of salt was one-half of 1 per cent., and the amount of salt water injected subcutaneously was sometimes as much as a quart at a single injection. In one instance, during an illness of several days, as much as thirteen quarts was subcutaneously injected into the cellular tissue, principally that of the abdominal wall. This process of subcutaneous injection was known as hypodermaclysis. The purpose of the hypodermaclysis was to maintain the volume of the blood. The diminished volume of the blood is directly the result of the waste of its liquid portion or serum into the alimentary canal. In this serous discharge, flakes of intestinal

mucous gave the name of "rice-water discharges" to the bowel evacuations, the particles having a resemblance to grains of rice. The general inflammatory state of the intestinal mucous membrane, throughout its entirety, drains the blood of its liquid portion rapidly, and collapse due to stagnation of circulation quickly ensues.

The remedies mentioned are only a portion of those tried, but there is no living advocate who to-day can point with unerring certainty to one single organic or inorganic substance, howsoever administered, that can be safely depended upon in the treatment of Asiatic cholera. Both botany and mineralogy have been searched in vain for a cure for this disease.

The cause of this disease is perhaps accurately stated to be due to invasion of the blood and, secondarily, of all the tissues of the living organism, by toxins or ptomaines, which originate in the upper portion of the small intestine at the early stages of cholera. These products of organic activity, whether of animal or vegetable organisms it is here unnecessary to debate; but these noxious products enter the circulation through the villi of the intestine and rapidly and desperately poison the blood. It is clearly proved that the disease is the result of general blood poisoning from an intestinal origin. Whatever the chemic nature of the poison may ultimately be found to be, may be safely left to the bacteriologic laboratory. The practical and intensely important part that remains for physicians seeking to cure patients in times of this disease is to realize how much, as well as how little, it is within human power to do. The human organism is prostrated by a fierce and deadly poison. This poison is in the blood and in the cells of the tissues, and its work of destruction is quickly and effectually accomplished. Reflectively, to say nothing of experimental research, it would seem to me that the rational and only course that could be advocated with scientific assurance of relief is to, as far as possible, literally cause to be removed these products which are death-dealing to the body in which they happen to be found. Now, in this same reflective mood, think for a moment and try with me to determine whether it is possible in such conditions as produce the symptoms of Asiatic cholera, it is safer to introduce other poisonous products to neutralize the noxious elements in the blood and cells, or whether it is a better process to, without the introduction of additional foreign substances, remove what we already find in the blood. To make this proposition clearer, it could be stated in another way, namely, the body is already bearing a crushing burden; shall we add other foreign substances as an additional burden to the load already carried? The principle seems to me to be at fault. The principle is the principle of allopathy, but in the light of facts is it a safe principle to follow? It is reasonably scientific to produce in the laboratory, definite results in vessels of glass by the use of fixed reagents; in the organic laboratory of the living body, no such definite results can be demonstrated. The vital principle is an entity which enters into the formula and may be represented by the unknown quantity  $x$  in algebraic equations. Great and laudable efforts have been made to prevent as well as to cure this disease by inoculation.

Ferran, of Valencia, Spain, thrilled the world ten years ago with his proposition of a universal cure

for this disease. His glory was then at its zenith. His fame has long since faded. So obnoxious became his proposition to the government of Spain that laws were adopted to suppress Ferran's cholera inoculations.

A worthy colleague and laborious investigator, Professor Haffkin, of Pasteur Laboratory fame, proposed a modified inoculation for the prevention and cure of cholera in 1892. A reporter of the *New York Herald* was inoculated at the Pasteur Institute, and with credentials sent to expose himself to Asiatic cholera at Hamburg in September, 1892. The same reporter had been similarly inoculated by Ferran in 1886 and had the courage to make further exploits in behalf of his newspaper, at Hamburg. A very widespread opinion prevails in America that the exploit of the *New York Herald* reporter during the ten days' stay as a nurse in the Hamburg hospital, constitutes a proof of the validity of Haffkin's claim, but the scientific world of Europe knows differently. *En passant*, it may be interesting to state at this place that further experiments have been made by Professor Haffkin in India with the cholera inoculations and, unfortunately for the proposition, reports have recently come to me from reliable medical sources, that a greater percentage are attacked with cholera who have been previously inoculated than of those who have not been inoculated. This subject of prevention, however, is to be discussed by me in a paper to be read before the Section on State Medicine.

The result of prolonged reflection, covering many years, and the observations resulting from personal experience in the cholera epidemic in Europe of 1892, is the conviction that there is provided in the laboratory of the universe a remedy which surpasses the results of human ingenuity as much as does the sun surpass in brilliancy the light of the artificial lamp. The all-pervading and all-wide remedy, the greatest product of omniscient nature's laboratory, which alone can cope with this pestilential disease of the human race, is nothing more and nothing less than the unmatched, unmatchable  $H_2O$ . Pure water is absolutely the only trustworthy cure for cholera, and if it came at a great price it would probably be more greatly valued. The human organism is so constituted that if it is assisted by  $H_2O$ , every morbid element may be eliminated out of its domain. The acutely poisoned body quickly recovers its equilibrium and its harmony of action as soon as the processes of elimination can remove the invading poison. In the construction of the mucous lining of all the accessible cavities and channels it is prepared by an undiscernible law to successfully resist the entrance of every form of organism. The products of organic action alone are able to pass into the blood. If sufficient quantities of pure water, of a suitable temperature, are introduced into the body through the natural channels, it is actually possible to wash morbid products as well as organic form of life, out of the human body. The mouth gives entrance to the causative germs in Asiatic cholera. That is quite conclusively established. The locality of the development and formation of the toxin in the earlier stages is determined to be in the upper end of the small intestine; and from experience, as well as from the powers of reflective analogy, there is no doubt that the system can be saved from death if the morbid entity, the germ, is literally deluged away from the

alimentary canal by the copious use of a remedy that can not be of the slightest danger to the victim. The amount of water to be used varies in different cases. It is impossible to use too much; it is possible to use too little. From the earliest moment that the patient is seen, the propositions should be, first, wash the whole alimentary canal with pure water; wash the lower portion by introducing irrigations of warm soapsuds or merely warm water into the colon sufficiently frequently and sufficient in quantity to cleanse that portion of the bowel effectually. The frequency of washing that portion of the bowel which is accessible from the rectum should be one, or two, or three, or four times a day, according to circumstances. At the same time from one to ten quarts of warm pure water mildly medicated with peroxide of hydrogen or hydrozone should be administered at regular intervals, during the day, as the prescribed remedy by the mouth. If the patient vomits, very well. Immediately re-introduce the quantity of water that was vomited. No harm can be done in any case, and if it is possible to save life it is possible to save it through this method. It is the quickest and the surest method of exciting the activity of the kidneys, and is the safest. It is the rational and effective measure for maintaining the volume of the blood. It is the scientific process by which to establish cutaneous circulation in the capillaries.

The use of simple and useful hygienic measures are the same as in other prostrating diseases. Patients should be fed with regularity at not too frequent intervals, giving the proper time, between administrations of simple food, for its digestion. The use of appliances for maintaining the heat of the body are not to be neglected.

The precise details of the method of treatment indicated at this time will be forthcoming in a subsequent paper.

100 State Street.

#### DISCUSSION.

DR. HOLLISTER—I found, during an experience of treating cholera in at least four marked invasions in this country, long before I knew anything of germicidal effect, that there were two substances which in my own hands were very satisfactory. The one was that of the vegetable in solution, tannin mixture, and the other the stimulating influences of cinnamon. These were reinforced by copious injections of water, and drinking also moderately strong infusions of cinnamon tea, a matter that seemed to be of decided benefit to my patients, with the injections of large quantities of water holding tannin in solution. It has only been within three or four years that I have come across the fact that either of these remedies is markedly germicidal upon the bacilli. This has been stated by several of the experimenters in connection with the treatment in Germany during the ravages of the cholera there. While water is of use in washing the alimentary canal, if we have these germicidal remedies it seems to me that the water treatment alone is not only necessary, but that we should also obtain the benefits to be derived from the others. In the irritated conditions of the alimentary canal, in infants, the remedies used seemed to me thirty years ago to have a peculiar effect in reducing the irritations.

#### LEUCOCYTES AND NUCLEINS.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY T. O. SUMMERS, M.D.

ST. LOUIS, MO.

I believe that St. Luke was the only physician upon the Apostolic Board, and that he is the generally accredited author of the Acts of the Apostles,

in which, describing the visit of St. Paul to Athens, he declares parenthetically this very remarkable historic note:

"For all the Athenians and the strangers that were there, spend their time in nothing else but either to tell or to hear some new thing." And this neophilism which the great Apostle of the Gentiles has given as an historic character to the "City of the Violet Crown," has descended unto us of later days, and it may be said with truth that among all the workers in the great field of science, medical men are most eager for discovery and most earnest in the search for the ever-unfolding mysteries of truth. And notwithstanding the fact that this spirit of investigation has often been held up to us by those who profit by our labors, and yet are ever ready to sneer at our methods, as the "*opprobrium medicorum*," it will be a sad day in the history of medicine when we care not to "hear or to tell some new thing."

It is to a new departure in therapy, developed by recent investigation, that I direct your attention in this paper. There is nothing which has so distinctively characterized the trend of modern therapeutics and separated it from the empirical methods of the past, which has crowded our materia medica with vast masses of useless rubbish, as the contribution of physiologic products to the control of disease. It is strange that we have moved so long in the floodlight of physiologic discovery, thrown upon us by the microscope, the spectroscope, and the ingenious apparatus which makes our laboratories more wonderful to the untutored mind than were ever the alembics of alchemy to an age of romance and superstition; it is passing strange, I say, that we have so long overlooked the very principles upon which alone a scientific system of therapeutics could ever be established—the functional relations of the cellular elements of the organism.

As long ago as that stormy time in the history of the British Association, when the Thompson-Tyndall prayer-test was convulsing the religious and scientific world, a no less interesting discussion grew out of that contest upon the subject of spontaneous generation. So strong was the antagonism developed, that it affected even the terminology of physiology. Dr. Lionel S. Beale, the recognized champion of the "orthodox" party, clinging to the principle of "vital force," and giving to the blastema of the ultimate physiologic unit of the organism the name of bioplasm, while Professor Huxley gave the name of protoplasm to that which he and all of his school recognized as the physical basis of life. Nothing then was known of the exact structural and functional character and relations of this peculiar cell substance, which appeared to act so differently under conditions apparently the same. It remained for later physiologists to show just what part this ultimate vitalized material played in the great drama of physiology. It was found that both these great scientists were correct, but viewing this cell-blastema under different conditions, their definitions differed accordingly, yet led up to the same result as in the case of Copernicus and Ptolemy, or to speak poetically:

"Like that target discussed by the travelers of old  
Which to one appeared argent, to one appeared gold;  
To him ever lingering on doubt's dizzy margin  
Appeared in one moment both golden and argent."

The first step in what may be called the new

physiologic system was taken, when with the improved mechanism of the microscope, it was demonstrated that of the two kinds of corpuscles which float in the plasma of the blood, the larger or white corpuscle, the leucocyte, was in every respect a perfect cell, possessed of a cell wall, which Dr. Beale distinguished as "formed material," a blastema or plasmic granular substance, in which floats a body called the nucleus. How many of these may be thus involved can no more be estimated than can the problems of time and space be solved by the finite mind.

The next step toward establishing our new physiologic system, was taken when the leucocyte was found to be the real unit of the organism, the agent through which all nutrition is accomplished. Up to a very recent date, it was believed that all the nutritious material which had been operated upon by the digestive agents, passed directly into the general current of the circulation, floating freely in the plasma of the blood till it reached the capillaries, and then by a reversed osmotic process was taken up by the individual tissue cells, only that part being taken up by them which was necessary to the support of that structure represented by the cell, and the rest passing on in like manner to the other structures until all parts of the organism were nourished.

The red corpuscle was recognized as the oxygen carrier of the system, and the eliminator of carbonic acid, but neither the origin nor the function of the white corpuscle was in the least understood by even the most skillful observers. Later investigations, however, proved the identity of the leucocyte with the lymph corpuscle, which was itself supposed to possess as the simplest original cell, metabolic functions. This gave a new importance to the leucocyte, and when to this was added the recognition of the pus corpuscle in retrograde metamorphosis, as nothing more nor less than leucocyte under altered conditions, it was not long before its true significance as the real tissue-builder of the organism was fully established. A peculiar movement of the leucocyte as it goes along through the current of the blood, had long been noticed, called on account of its resemblance to that of the amœba, the lowest form of animal life, the amœboid movement, by which it changed its form apparently at will, becoming often so elongated and slender that it slipped through the walls of the blood vessels and held high carnival in the surrounding tissues. All this pointed to some mysterious power or function as yet unrevealed to the eye of the physiologist. A closer study of its morphologic characteristics proved that there were several forms of leucocytes, differing in the number of nuclei which they possessed. The simplest, those having but one nucleus, were called mononuclear, those possessing two or more nuclei, were called multi- or polynuclear leucocytes. In these it was seen that the amœboid movement was most active. Vierordt, who has made the most accurate observations upon the blood, of any other physiologist, perhaps, found the numerical relation of the leucocytes to the red corpuscles to be in health in the ratio of 1 to 671.

Now, we are prepared to understand the next step in the functional history of the leucocyte. These bodies differing in size, shape, and number of nuclei, were observed to swell up and burst, pouring out a plasmic granular mass, which appeared to be in a

state of active molecular vibration. The nuclei came forth from the breach in the cell wall with some of this blastema hanging closely around it, while the rest of the blastema, with the ruptured cell wall, floated off in the blood current. Where there were two or more nuclei, each one became rapidly a perfect cell with its nucleus and nucleolus, and in this way was established a great increase in the number of leucocytes. This process of cell proliferation, it will be seen, lies at the foundation of all nutrition. The next phenomenon observed was what might rationally have been expected to be established—the taking up by the leucocytes of the proteids which are delivered to the blood by the absorbents after digestion is complete.

As soon as these proteids get within the walls of the blood vessels, they are immediately attacked by the leucocytes and taken into their cell walls by that osmotic process which is the basis of all physical action in the organism. Mingling with the blastema of the leucocyte, these proteids become suffused as it were, with a certain molecular activity imparted to it through the influence of the nucleus, something like that observed when an electric current renders nascent certain chemic agents that without it are negative or inactive. It is this vitalized pabulum to which physiologists have given the name of nuclein.

The next step in physiologic evolution is the appropriation of this pabulum by the individual tissue cells of the body as it passes through the capillaries. And here it must be noted that no assimilation of any nutritive substance (except of inorganic origin, as water, etc.), can take place through any medium but that of nuclein, and it is in the multinuclear form of leucocytes that we find it developed. It has long been known to physiologists, but its wonderful place in the economy of the organism was never known until the close study of the leucocyte developed its origin and function, and in this way cleared up some of the most hidden mysteries of the organism, and placed in the hands of the therapist, the most wonderful agent of therapeutic power yet known to scientific medicine.

To return to our panorama of nutrition. Seeing then the proteids must all report to the leucocyte and be stamped with this nuclear influence before delivery to the several tissues, the bursting of the leucocyte is readily understood, for by this means the nuclei are set free to become new cells, and a great quantity of this cellulized tissue pabulum is poured out into the circulation, bathing with food every hungry cell of the several tissues through which it floats, each cell taking up that which is necessary to its molecular activity and returning to the current that which belongs to other and remote tissues of the organism. This conversion into tissue through the circulatory system, of material lifeless in itself, is the most wonderful phenomenon presented to the human mind. We can not explain the affinities by which certain kinds of pabulum are accepted and others rejected by the several tissue cells of the body, any more than we can explain the affinities between the sexes, often so seemingly astounding. We know this, however, that the change which goes on is the elaboration of a vitalized or cellulized substance, which is capable of entering at once into tissue as soon as it meets the various cells which have this power of elective-assimilation. This primal cellulized pabulum has,

therefore, been appropriately called nuclein, from the mode of its generation, and when operated on by the individual tissue cell it becomes proto-nuclein, after the analogy of Professor Huxley's nomenclature, which represented its real origin. This substance is rich in phosphorus, and has been separated in active form from the lymphoid structures of the body, as we shall see later.

We are brought now, face to face, with one of the most formidable problems of physiology, the solution of which will destroy many of our old pathologic ideas, upon which so many therapeutic systems have been wrecked. Up to a very recent date in the history of pathology, leucocythemia was considered a specific disease. Upon the *post hoc propter hoc* principle of medical philosophy, the rush of leucocytes to any point of irritation was regarded as a feature, or even a distinct stage of the disease. How vividly can the memory of some of you recall the old professional saws, as they were called by those of us who sat at the feet of the Gamaliels of those days, among which there was none more familiar than the *ubi irritatio ibi fluxus*. We answered almost all our questions upon inflammation with this single axiom, as we believed it. Often have I heard the venerable Gross straighten his lofty form and declare in a stentorian voice, that inflammation consisted, pathologically, of the rapid afflux of leucocytes! How startled would he be to learn that modern physiology has demonstrated that that rapid afflux was Nature's reinforcing battalions! Every white blood corpuscle that gathered about that point of irritation bore with it the materials of repair, and as still later investigation has proved, also the power of overwhelming toxic germs, themselves in their incipency, and protecting the organism against their poisonous and deadly exudations.

As to the phagocytic action or cell-eating power of the leucocytes, which has been strongly claimed by some observers and as strenuously denied by others, it is, after all, a mere question of difference in the manner of destroying toxic germs, which has developed antagonism among physiologic observers. It is, as I have upon a previous occasion already remarked, not at all necessary that because the physiologic or pathologic function of one cell is lost in that of another, we should, in speaking of such action as a phagocytic or cell-eating process, imagine a mouth and teeth and all the paraphernalia of mastication, deglutition, etc. The result is the same, whether the pathologic germ is swallowed, destroyed or neutralized; so long as the cellular influence of the leucocyte is the agent which accomplishes this, it is immaterial whether we use the term "phagocytic" literally or metaphorically, but notwithstanding all the adverse criticisms of the word as used in this connection, there is none given us which more emphatically expresses the idea we wish to convey; the difficulty of nomenclature is too great to lightly reject so expressive a word which as bacteriologists and morphologists all admit, does certainly most vividly express the primordial condition of which this is the physiologic analogue. In its last analysis, after all, it is the molecular disturbance produced in the germ that deprives it of its toxic power. This we know will effect even chemic action. Upon this, all fermentative processes depend.

Isomerism is another example of the effect of molecular arrangement or disarrangement. Where

can you find two substances more distinctly different than sugar and gum arabic, and yet they are exactly the same in composition and in the proportion of elementary combination, the difference in arrangement of the molecules being sufficient to account for the difference in chemic and physical properties. With these examples before us, and I could, if time permitted, bring out many others equally as striking, it is very easy to see how the slightest disturbance of molecular arrangement in any germ will deprive it of its specific character, and by investing it with certain cellular elements, emasculate the most deadly of toxic bacilli and send them harmless through the blood currents of the organism. Having, therefore, found that it is within the leucocyte that all protozoic material is developed, that upon the proliferation of the leucocyte all assimilation depends, it is but a step further to establish the action of the leucocyte in resisting the effect of toxic germs, as well as divesting them directly of toxic power. It would perhaps be more accurate to define this action as a supporting of the elementary structures of the body to such an extent that they are capable, of themselves, to overcome the pathologic influences which are being continually introduced into the organism. To those whose daily experience brings them face to face with the awful side of human life, I think I can appeal with emphasis, when I state that there is scarcely a breath we breathe, or a drop we drink, or a morsel we eat, that is not charged with the germs of deadly disease, and if there were not in our organism a distinct provision made for the resistance of such germs, to use a Pauline expression, we should "die daily." When the tocsin of disease is sounded through the organism, it is the rushing of the leucocytes that constitutes the first physiologic response to directly resist a toxic agent, or supply the structure attacked, with material for nutrition or repair in case of lesion. And yet there are still those among the ranks of intelligent practitioners who consider the increase of leucocytes as an element or phase of disease itself, instead of nature's effort to support her crumbling battlements. At this stage of my argument, I shall, upon the strength of what may be microscopically demonstrated to be the function of the nuclein-charged leucocyte, make an assertion which, I have no doubt, will be considered perhaps too arbitrary. It is, that whatever of so-called specific effect lies in the antitoxin obtained from the immunized animal, as opposed to the bacillus and the toxin of diphtheria, is accomplished by the excitement of leucocytosis and, after all, the end is reached by the same physiologic process.

The ultimate aim of all antitoxic agents must be overwhelming of the toxic element of the germ, and this can only be accomplished by a great excess of physiologic tissue building material. Let us observe the process by which this antitoxic effect is brought about. In the first place, the physiologic relation of proto-nuclein would, naturally, preclude the idea of its action as a direct specific antidote to a specific poison such as that observed between chemic agents, or even physiologic antagonists, as for instance, the hydrated sesquioxide of iron against arsenic, or atropia against morphia, or chloroform against strychnia. Were this the principle of the functional activity of proto-nuclein, its therapeutic range would be limited to such an antagonism, but I am prepared to show, by careful experimental records, its effect is first ob-

served when the system has been thoroughly charged with it, thus preventing the expression of the toxic agent by a preoccupation of the nutritive field, and an investment of the attacking germ. I have often noticed a leucocyte thoroughly charged with original nuclein adhere to the cell of a sarcoma, and after bursting itself, send the round cell floating away in the field crenated and almost emptied of its contents. Such effects have been observed also upon the blood after days of treatment with proto-nuclein. This appears to me to be the very *ultima thule* of therapy; and the question will be, has been, very naturally asked after such developments: "If such be the power of a substance capable of investing, controlling and overwhelming toxic agents, where is the limit to its action?" If I spoke the truth boldly, as it should be spoken, I should answer that, properly applied, I can see no limit to its resisting power. When, side by side with my own experiments, I have observed what I admit to be the wonderful effects of antitoxin in the organism of the bacillus and toxin of diphtheria, I have nevertheless felt that proto-nuclein was as far superior to it in pathologic results, as the whole realm of pathology is greater than a single disease.

And now we come to the question of practical interest to the general profession, How is it possible to extract this delicate substance from the animal tissues? and its corollary, What are the methods used to preserve its cellular activity?

There are three forms of nuclein material now before the profession: 1, nuclein made from yeast; 2, another preparation of nuclein has been prepared which is taken from the animal organism by chemie methods, prepared in tablet form for internal use. I am not aware that this form has ever been prepared in solution for hypodermic use; 3, the third form of proto-nuclein is a product taken directly from the lymphoid tissues of the healthy animal, the thyroid and thymus glands, the brain substance within the area in and about the corpora quadrigemina, the pituitary body and pineal gland, the pancreas, spleen and liver. No chemicals are used in this process, the methods of extraction being purely physical, and the proto-nuclein is kept active by an investment of gum benzoin and milk sugar which preserves it indefinitely, just as the germ of a grain of corn is kept potentially active by its environment. The activity of the proto-nuclein may be easily shown by dissolving some of the powder in distilled water. After the sediment has settled, draw off the supernatant fluid and apply a drop of it to a drop of freshly drawn blood. You will see a most beautiful physiologic panorama, instantaneous photographs of which I have here for your inspection. Proto-nuclein is richer in nitrogen than the ordinary nuclein of the text-books. Its formula, as far as it is possible to be chemically accurate in quantitative analysis, is  $C_{29}H_{49}N_{10}P_5O_{32}$  differing by about one equivalent of nitrogen. It will be noted how rich in phosphorus this wonderful physiologic agent is.

So much, therefore, for its preparation and extraction. The most important factor in the problem is the answer to the questions, What will it do? What can it cure? What will it prevent? in the great battle between science and death. Were I to give free range to my own confidence in the therapeutic power and range of proto-nuclein as observed from day to day for the last six months, under the most favorable

circumstances and under the direction of experienced and authoritative clinicians, you would discredit even the demonstrations of this report. But if you will consider for a moment what a sweeping therapeutic power must belong to any agent which is the normal tissue builder of the organism and the direct antagonist of its invading toxic germs, you will see how difficult it is to limit its indication as a therapeutic agent. Its most pronounced results have been observed in tuberculosis, sarcoma, neurasthenia, tonsillitis and la grippe. In such cases it has shown a most wonderful power. In the hospitals of New York it has been used with general success in the following diseases, beside those already mentioned: diphtheria, neurasthenia, pernicious anemia, general marasmus and other cachectic disorders, fevers, etc. As to its dose and mode of administration, I subjoin to this paper full directions which have been carefully prepared from the closest clinical observations.

Nothing has been left undone to thoroughly test the practical truth of what has been theoretically claimed as a therapeutic power. I believe with others even more conservative and less sanguine than I, that it will mark an era in therapeutics. Such relationship between the pabulum and the individual tissue cell of the various structures of the body, seems to be the very last analysis of function in the human organism. We approach, as it were, the very *Shekinah* of physiology. Up to the time when therapy began to look to physiology for help, our whole system was a vast accumulation of clinical reports without one iota of determining philosophy—a vast labyrinth without an Ariadne thread to guide the returning footsteps of our reason. I doubt not that before the close of the nineteenth century, our therapists will look back upon the thousands of agents vaunted in the cure of disease, as the modern soldier gazes upon the spear and shield of ancient Greece and Rome. The simplification of physiologic methods has been followed most naturally by the use of those physiologic principles of therapy upon which the normal curative conditions of the organism depend, and without which no scientific system of therapeutics could ever be formulated.

## THE PHYSICIAN OF THE PAST, THE PRESENT AND THE FUTURE—A DEFINITION OF HIS SOCIAL POSITION.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY JULIUS KOHL, M.D.

MEMBER OF THE STATE BOARD OF HEALTH OF ILLINOIS; MEDICAL DIRECTOR OF ST. ELIZABETH'S HOSPITAL, BELLEVILLE, ILL.; MEMBER OF THE ST. CLAIR COUNTY MEDICAL SOCIETY; MEMBER OF THE ST. LOUIS CITY HOSPITAL MEDICAL SOCIETY, ETC.

BELLEVEILLE, ILL.

In this age of progress, when we behold a constant race for new discoveries in medicine and surgery, when nearly every day brings new surprises, it may not be amiss to pause and take a glance at our profession from a different point of view. May be we will discover that it needs a little attention in another direction. I admire every diligent worker, every untiring student. But with all this, the nobility of our profession must stand foremost. Our calling is not a business alone; neither honor nor the desire for dollars and cents alone are at stake. It is an exalted vocation. The unsullied social position of the

physician should tower high above his other achievements.

#### THE PHYSICIAN OF THE PAST.

It is only for the purpose of introduction that I will dwell as concisely as possible on the history of medicine, and the physician of the past. Some historians, among others Daniel LeClerc, have traced it into the remotest ages, as far back as twenty-eight hundred years before the Trojan war. The most of it is mythical, and it would be a waste of time, from a medical point of view, to analyze the fables of the ancients. Whatever was known to the ancients of medicine, rested in the hands of their pseudo gods and priests.

No doubt that at all times there was disease and suffering and that attempts at healing were made. The Bible throws no light on the subject of regular practitioners of medicine and surgery among the Jews. If we look around among their cotemporaries, we find the Aryans prominent. They inhabited for many centuries as a compact nation the great plains, the highlands of middle Asia. Like the history of nearly all ancient people, theirs is transmitted to us through their religious and their war hymns. They possessed no other literature. Their songs and prayers reveal to us their doings, their pleasures, their wishes, their joys, their ills, their knowledge and their ignorance. In the collection of their hymns, the "Rig-Veda," they implore the gods for help in sickness—not one special god—they name several, but most frequently the twin god, Aswin. Eventually, in one of their songs, the word physician appears. They sing: "Our wishes are many; the charcoal burner wants wood; the priests, gifts; the physician, patients." This shows for the first time in the history of medicine a distinct recognition of the physician and the separation of that science from the office of priest. Magic is also mentioned as a healing power in the "Atharva-Veda."

There is no doubt about the existence of the Egyptian priest-physicians. While the divine mission of Moses will not be questioned, nevertheless his knowledge of medicine and hygiene was obtained in the land of the Pharaohs.

The Phœnicians must certainly have had their physicians, and without the existence of some medical literature before Hippocrates, it would have been impossible for him to have left us so much information that, even in these advanced times, is of incalculable value and benefit to the profession.

Prior to Hippocrates, schools of medicine existed at Kos, Knidos, Rhodes, Kroton and Kyrene, and however primitive and imperfect they may have been, we must consider them as pioneers. With Hippocrates began a new era. What had been up to his time a mass of blind mystic empiricism, mostly in the hands of the priesthood, was by him for the first time in history, converted into a system, and when we consider the limited resources at his command it is wonderful how perfect he has made it. For centuries it was the only guide, and Galen who lived in the year 131, Celsus and others, down to Avicenna in 980, notwithstanding their renown, and the great works they too have left, were unable to add much to it. At last Paracelsus, in about the year 1500 introduced chemistry into medicine and thereby changed the whole system. About the year 1520 he destroyed by fire publicly, in the city of Basel, all the works of Galen

and Avicenna, indicating the final closing of the ancient methods of medical practice.

How much valuable medical history was destroyed at Alexandria by the fanatical Moslems will remain unknown to us forever. Even after Paracelsus, medicine was not looked upon as an independent scientific system. The church which monopolized all branches of science, was very slow in granting it freedom, and the students of theology in Sweden, and other continental countries, were compelled to take a course of medicine as late as the beginning of the present century.

During the Middle Ages the study of medicine, together with the other natural sciences, rested of necessity in the hands of the priesthood, and many were better versed in these branches than in theology. Students at the centers of learning in those days devoted nearly their whole lifetime to become masters of all sciences, so much so that in course of time regulations had to be adopted, and we find about the year 1200 the pious and learned monk Helinand, giving utterance to his feelings in the following plaintive words: "*Eccc querunt clerici Parisiis artes liberales, Aureliani auctores (sc. classicos) Bononiæ codices, Salerni pyridces, Toleti Dæmones et nusquam mores.*"

Later on, the practice of medicine, especially surgery, was by a decree of Pope Gregory forever prohibited in the following language, and confirmed later by Pope Innocent III. in the General Council of 1216: "*Sententiam sanguinis nullus clericus aut dicet proferat, nullus quoque clericus ruptariis vel ballistariis aut hujusmodi viris sanguinem præponatur, nec ullam chirurgiæ artem Subdiaconus, Diaconus vel Sacerdos exerceat, quæ adustionem vel incisionem inducit.*"

Regular physicians and surgeons had to fight their way against many obstacles, to bring about the emancipation of the profession. At best, the practice of medicine during the three hundred years preceding the present century was a mixture of science, theology, astrology, magic, witchcraft, superstition, spiritualism and a mass of other indescribable 'isms. It was empirical to a great extent. The last fifty years must be credited with having given to the world the exact sciences of medicine and surgery, and their emancipation has been completed.

We, their disciples, should rejoice to have lived to see this. With gratitude we should look back to the giants in our art who have preceded us. Imagine the clouds of darkness with which they were surrounded, often frustrating their best endeavors. Let us admire their diligence in delivering to us their literature without the assistance of the printing press. Let us give credit to those that preserved it for us during the Middle Ages, often mis-called the Dark Ages. Let us turn with reverence and admiration to the industrious monk in his lonely cell, through whose midnight labor we have had preserved to us the manuscripts of the ancients.

What would have been left to us if he had not saved those treasures from the destroying hordes of Alaric and Attila, the Gaul and the Saracen, in whose invasion of the then civilized Europe, the lifework of the sage perished with the handiwork of the peasant.

We are prone to censure these pioneers of science, but it is questionable, whether our most learned cotemporaries could have done more for medicine and surgery than those persecuted scholars of ancient days.

Looking over the history of Rome, we find that our days produce the same impostors as lived during the Roman Empire. Notwithstanding the teachings of Hippocrates and Galen, the special healing gods were appealed to by the best and most refined of those days. There was a continual pilgrimage to the temple of Petosiris, for astrological advice in sickness, regarding which Juvenal ironically exclaims as follows: "*Capiendo nulla videtur aptior hora cibo, nisi quam dederit Petosiris.*"

What difference is there between this and the modern Christian science healer, and kindred humbugs?

#### THE PHYSICIAN OF THE PRESENT.

But let us consider the obstacles surrounding the physician in our days. Quackery will never die. The Indian medicine man of the forests of undiscovered America, with his invocations and posturings, has but changed his name and garb and is with us now in the nineteenth century, stealing his way as a Christian science healer or sophist of some kind, into all classes of society; into the hovel of the ignorant poor and the palace of the rich and apparently educated. The quack and his victim will live forever. Ignorance and dishonesty will always seek the false, the mysterious and the superstitious. It seems impossible to educate the masses into an understanding and appreciation of the unerring laws of nature. The physician of to-day and of the future will have the same never-ending contention with charlatanism and ignorance.

I come now to consider the position of the physician of the present. Medicine and surgery are recognized by the entire civilized world as independent sciences, and we, their disciples being intrusted with their care and application have assumed, as the physicians of the present day in this immense field, the greatest of obligations and responsibilities. We have at our command the whole earth and its surroundings, and have the right to press all into our services, but with these rights are manifold duties which I shall attempt to enumerate in part.

The duties of the physician to himself, his patients, and his fellow-practitioners, are well laid down in the rules and regulations adopted by this ASSOCIATION many years ago, and they come as near perfection as any set of laws known to me. For the purpose of brevity I will not dwell on them, but will at once come to the consideration of the duties of the physician in regard to some of the great social questions of the day.

It may be asked, What has the physician to do with the great social questions? I answer, His relations to such questions place him on a footing equal to, if not above, that of the spiritual advisor. No one comes in daily contact oftener with his fellow-men than he. He is their firm friend and recognized superior in matters pertaining to a knowledge of nature and her laws, which he is in duty bound to promulgate every day. When the great Creator of the universe made laws, in silent obedience to which the stars and heavenly bodies move, laws which all nature obeys, he formulated a code of law, which even man, the prince of creation must obey.

But I hear the question, Is not this the province of the church and State? I answer, yes. They have their part to perform, but whether or not they do their duty is a question about which there is grave

doubt. Looking at the State and the enforcement of its laws by the courts, it is apparent to every thinking man that it falls far short of performing its great duty. As to the church it seems to have lost its hold on mankind to a large extent. Self-styled evangelists travel through the land, seeking by preference the large cities. Their discourses are sensational, for their hearers love sensation. After a season of pretended exhortation, and addresses made to men only, they shake the dust of the city from their feet and depart, their pockets well filled, leaving behind them only a cloud of smoke. The churches are turned into club-houses; sweet songs, sweet music, (of a nature mostly unsuited to the worship of the Creator), mouth preaching is all that remains, and only the dance is lacking to make the entertainment complete. The masses of to-day want entertainment. It does not matter what is given them. They are ready to applaud Ingersoll to-day, the traveling religious mountebank tomorrow, and Barnum's show the next day. It is only a modified repetition of the cry of *civis* and *plebs Romanorum*, during the declining period of that mighty empire, "*Panem et Circenes.*"

The honest pastor who educates the youth of the land in morality, in order to make good men and women of them, is at a discount. Church dignitaries, high and low, quarrel among themselves to the detriment of their flocks. If any one doubts the poor outlook for help to mankind from the church, let him cast a retrospective glance at the monumental farce of the present century, the Religious Parliament, held at Chicago during the World's Fair. Unless the spirit of a Peter Cartwright, Marquette, Father de Smet, Prince Galitzin or others, of like character reappear, not much can be expected. Not even the last resource of the masses, the salvation army, will avail.

Let the doctor, the emancipated physician of the nineteenth century, with a grateful heart do his duty.

I say the physician must take a firm stand on all social questions. When he is girded with the armor of the never-erring laws of nature, he is ready to fearlessly take up the gauntlet against any antagonist. Let me begin with the laws of the propagation of the race. It is not the purpose of this paper to give a dissertation on them; they are prescribed by God, the church and the State. That which comes within the province of the physician is of a twofold character. On the one hand, he is called on to remove physical obstructions which stand in their way, but oftener, in our days, he is called upon to interfere with the laws of nature. The first one belongs to one of the proudest duties of his profession; the other is the offspring of Satan and alike detestable and abhorrent.

The duty of the physician upon being consulted by the moral leper who would prostitute the noble science of medicine and surgery to the foul purposes of such wretches is plain. He should stamp upon such intention and prevent by all means in his power the consummation of the greatest crime against nature. Procreation impregnates all nature and all natural laws, and a society which tolerates the violation of these natural laws deserves the fate of a Sodom and Gomorrah.

About three years ago, a number of so-called learned people held a convention in the city of Detroit, Mich., in which the subject of interference and prevention was discussed by some male and female

physicians there assembled, and the disgraceful spectacle was presented of a large advocacy of these unnatural and abhorrent methods. There was only wanting the presence of the majesty of hell to furnish the diabolical perfume befitting such a discussion. Let no reputable physician soil his hands and disgrace his profession for filthy lucre. These foul practices once taking a firm hold on society destroy mankind, womanhood, the family and the State. The history of the world is filled with the proofs of their dire results. A once powerful prominent nation of Europe, where the system began about one hundred years ago, goes begging to-day for a ruler and the end of it has not yet come. I deem it to be the highest duty of the true physician to destroy all literature aiding the practice, whether called by their true names or under the delusive title of tokology, etc. Such literature is properly called "Satan in society."

But enough; let us proceed to a further branch of our inquiry. What is the duty of the true physician regarding the question of the emancipation of woman?

Man has his place in the world, so has woman, and nature has drawn the line. Man should be the protector of woman. In all the ancient nations, which can be held up as an example, the Jewish nation seems to have taken the proper stand. There the woman was conceded the place belonging to her. Christianity has done the same thing somewhat improved, but step outside the boundaries of Christendom and the woman is found to be a slave. Physicians should unite against the modern false emancipation of woman, for they know it is a perversion of nature. Protect the woman, give her a chance to sustain herself honorably when those to whom she has a right to look for sustenance neglect to do it, but do not delude her and assist her in the belief that she is man's physical equal. Put her on the same footing with man, with full-fledged rights and privileges, let her contest on a physical plane with man, to sustain herself, what will become of her? The physician must know the ills and evils that will beset her. There have been and there still are, very many great women who will forever shine in history, empresses, queens and others in all stations of life, among them the sisters of charity, the physician's best friend and helper. There were the brave women of Saragossa, and our own great American women of the wars of independence and of our late war for the Union. I doubt if all these great and good women would join in the cry for woman's emancipation, in the modern sense. The physician should be the daily teacher to refute the falsehood for the sake of woman. The physician can never approve of the perversion of the laws of nature, and it is believed that such laws stand forever as a barrier to the attainment by woman of that equality so much desired by the agitation of the present generation.

And now the liquor question. Wines and liquors are the gifts and products of nature, then why make war on them, instead of upon their abuse? The physician needs them. He knows the genuine from the adulterated, by virtue of his knowledge of chemistry and pharmacy. Prohibit a legal traffic in wines and liquors, and the physician, his patient and the public in general are at the mercy of the smuggler. The physician should advocate laws for inspection of food and drink. He should see to it that these absolute necessities of mankind are pure. He should

never lend his aid to the enactment of prohibitory laws because they are unnatural. Nature gave to man the earth and its contents for his use, but not for its abuse. God created man to be like him, not to be muzzled like a wild beast, to prevent him from harming himself with his Creator's gifts. A godlike man in chains, guarded against himself, protected by law and force from his own acts, presupposes that he is affected with a species of insanity, which requires confinement and curtailment of liberty. Physicians, the students of nature, can not sanction laws so unnatural. If the teachers of mankind have neglected their business, do not help them to patch up their work with nostrums, but as true helpers of mankind point the way to obedience to those natural laws by which mankind must ever be governed. The physician should be found on the side of sound reason, performing his duties regardless of the cries of fanatics or the claims of quacks.

These are some of the more important duties of the physician, considered with reference to his social position. Time forbids a discussion of the numerous minor duties.

I do not wish to be understood as advocating that the physician should seek controversies on the subject of his duties. His duties are of such a nature that they do not admit of public discussion, except with and by physicians. The nature of his duties, reaching as they do into the privacy of the home, preclude particular open discussion, and permit but of a generalization when presented for public inspection.

The object of touching on these social questions is to define the position of a physician toward them, as he is above all others the intimate friend as well as helper of the family, the foundation of all human government. Intimately connected as he is with the inner life of his patients, he should above all things strive to be in the right, the just and natural side of all matters which come within his sphere.

The physician of the nineteenth century must not allow future generations to think of him as narrow and contracted, but history should record him as a man of broad and upright views, a scholar, a sage, whose best thoughts and aspirations were for the advancement of the noble science he had espoused. His care for his patients, his thoughtfulness and watchfulness for them requires his most earnest examination of all their surroundings and the principles of hygiene and sanitation should receive his closest attention; he must make war on the sins committed against them daily; privately, when he comes in contact with them in the case of his patients; and publicly when his duty as a citizen, having in view the welfare of his fellow-man requires it.

Mankind needs much instruction and, considering our boasted learning, it is astonishing how little the principles of hygiene are understood by the masses; how little attention is paid to pure air, pure water, pure food, clean houses and proper ventilation, as medical assistants. What a field for the physician, and in a direct line with his work socially! It is wonderful what can be accomplished in this direction by well-directed action on the part of the physician; adapting himself by reason of his close relations with his patients, to their needs and wants, he becomes at once the purifier of their minds, their bodies and their houses, a position socially to be envied by all men.

## THE PHYSICIAN OF THE FUTURE.

The first duty of the physician is to sustain himself in the position heretofore described, and to accomplish this he must be equipped with a thorough education. The standard of education must be raised. It is true that nearly every medical college is proclaiming that necessity, but such proclamations are but as traps for the unwary, and it is expected that by the mere noisy declarations of the necessity they will be credited with having accomplished the fact.

Before we can speak of a medical education we must look to the education of the student, and that question solved I have no fears for the professional education. When this country was new and there was a demand for physicians, it was quite natural that this demand should be supplied. I will utter no word of censure against the medical school of the past. The profession of medicine and surgery in our country in the past can boast of a great number of pioneer giants. I would name some of them out of respect, but since they are known to the members of the ASSOCIATION I will, for the sake of brevity, deny myself that pleasure. We are now, however, on the threshold of another and different period, and this ASSOCIATION must place itself on record as indicating the path which is to be followed in the future. This ball, the earth on which we dwell, is growing smaller, figuratively speaking, day by day. We are surrounded by a world of intelligent neighbors. The oceans that separate us from other continents have lost their terrors. We must become the equals of other nations in literature and science, as well as in trade and commerce. Can the American physician and surgeon afford to be behind his brother of the old world? Never!

The time when the green country lad, however intelligent and ambitious, or the man advanced in years, can take up books at any time and begin to read law and medicine is past; the education of the professional man of the future must begin early in life. At the age of 10 years the boy intended for a professional career must be able to read and write correctly and he must know the rudiments of arithmetic (I am describing now the education of the student in Europe). He has by this time had a glimpse into history and geography. At the age of 10 he is removed from the common schools and enters into a higher grade. There the study of Latin and one other modern language begins, together with higher mathematics, history, geography, botany (botanical gardens are attached to these schools in many places), zoology, etc. By the time this boy is 14 he is a pretty well educated fellow. Other studies then follow in still higher graded schools, and other languages are added to his studies until at the age of 17 or 18, our European student, if he has any of the ambition of youth is a highly educated person. Give us a young man brought up in this way. Give us one who has in addition to that, or in lieu of some of the unnecessary branches, pursued those taught in the manual training schools (called polytechnic schools in Europe), and you have the only student fit to take up a profession.

Our future American student of medicine or law will have to be brought up in just this way. Hundreds of them pursue this course now. One prepared in such a thorough way can accomplish more in two years of professional study than the one not so pre-

pared in four or six, nay even in a lifetime. Give us the well-prepared student, and the bogus medical schools will die without legislation, for the want of students. I think, in fact, I know, that many of our schools of medicine are good. They exhibit an honesty of purpose which is commendable. Let the AMERICAN MEDICAL ASSOCIATION assist in furnishing them the proper students. Legislation is now pending in several States which will, when perfected, take the entrance examination to medical colleges out of the hands of the college faculties. This is a step in the right direction. In one of our States this move will be inaugurated in the near future. It must only be borne in mind that in this, as in all progressive measures, radicalism is to be avoided. The truth once conceived can force its way to a triumphant acknowledgment only by sensible measures. Step by step this must be accomplished. Step by step, just like the education itself. The wisdom of those who are by law empowered to regulate such matters will have to be exercised to its highest degree, and justice and impartiality must form the basis of all their actions.

With chemistry and the microscope the study of the germs—histology, physiology, pathology, etc., have been revolutionized. How is it possible for the future physician to combat the problems of nature and disease; how can he expect to master the study of his profession with a few courses of lectures? It is an absurdity to suppose it. It requires a lifetime and a foundation well laid. Twenty-five years hence when we observe a physician's sign, we must expect to find a true physician; the pill-peddler with his saddle-bags will only be known in history.

The future doctor will have his private laboratory. He can not even prescribe for a simple case of rheumatism without a preceding chemic analysis of the excretions of the body. The future doctor will not permit every ambitious manufacturing concern, as is customary at the present day, to do his thinking and lull him into the false habit of lazily prescribing their stuff. The future doctor will not prescribe before his diagnosis is complete. He will examine the sputa, the ulcerated throat, in short, everything else, to make sure what he is dealing with. Chemistry, the microscope, electricity, and all the powers and resources of nature will be pressed into his service. What is done by only the few to-day will then be the universal practice.

Medicine will then, indeed, be a science, a profession. The man with an 'ism or 'pathy will also vanish. He is only the product of ignorance and perverted education. Science has no 'isms. Facts alone count in science. Truth has no barriers; it penetrates everything, and the spirit of truth rules the universe. It may be hidden, it may be trampled upon, but it will come out victorious in our science as in everything else. The physician of the future must follow the truth. The laws of nature are his guide and they will never mislead him. Honest study, honest investigation will lead to his individual success and to the honor of his profession. The well-educated and, I hope, the well-bred physician will be an ornament to society. He will be the people's friend and advisor. When he enters the house of his patients, or when the inmates of the hospital hear his steps in the corridors there will be rejoicing. His very presence will inspire confidence and hope in them. They will willingly submit to

his orders and instructions. They will read truth and consolation in his countenance. In return, he will enjoy his vocation. His life, though full of hardships, will bring pleasures that riches can not buy, and when his career on earth is ended and he closes his eyes in that sleep that knows no waking, I am certain that his heart will be at rest. He has, indeed, faithfully served both God and man.

## SOCIETY PROCEEDINGS.

### Michigan State Medical Society.

*Thirtieth Annual Meeting, held at Bay City, June 6-7, 1895.*

#### FIRST DAY—MORNING SESSION.

The society convened in the Madison Avenue M. E. Church, and was called to order by the PRESIDENT, DR. H. O. WALKER, of Detroit.

Prayer was offered by REV. M. C. HAWKS. This was followed by an Address of Welcome by ex-CONGRESSMAN T. A. E. WEADOCK, who trusted the meeting would be one of great intellectual profit to those in attendance. He said that Bay City considers it an honor to entertain such a distinguished body of men. He spoke of the pulpit, the bar, and of medicine, holding that they all aimed to uplift mankind. The professions should act together for honorable and honest dealings. He closed his remarks by welcoming the society to the city.

DR. A. F. HAGADORN, on behalf of the Bay County Medical Society, then extended a hearty welcome to the city. He said a very warm feeling exists in Bay City toward the State body.

The Executive Committee then reported the different arrangements that had been made to entertain the society outside of business hours. The Masonic and Bay City Clubs were accessible; the steel and wooden shipyards were open; the sawmills and the salt blocks might be visited, and the carriages of the people of the city would be at the disposal of the visitors Friday morning at the hotel doors to take them around the city.

The SECRETARY, DR. CHARLES W. HITCHCOCK, of Detroit, read his annual report. It told of the benefit to be derived from the passage of a bill to create a Board of Medical Examiners, but inasmuch as Governor Rich had just vetoed the bill, that portion of the report, he said, would have to go for naught. The Secretary further reported that owing to the inaccessibility of portions of some counties, it had been impossible to get local societies organized. He cited one case where one side of a county had a well-organized society, while the doctors of the other side were not members because they could not conveniently attend the meeting. Dr. Hitchcock urged that more effective work be done by forming a society in every county in the State.

On motion, a committee consisting of Drs. Boise, Connor, Patterson, Newkirk, and the Secretary, were appointed to devise some means to increase the membership of the State Society.

The report of the TREASURER, DR. WM. G. HENRY, of Detroit, was read by the Secretary, owing to the fact that Dr. Henry was confined at home by sickness. The reports were adopted.

During the morning session the Committee on Admissions reported favorably on several applications for membership.

The Committee on Necrology gave short sketches of twelve deceased members.

Under the head of reports of Special Committees the following were adopted: 1, to memorialize the Legislature in reference to the bill for the prevention of blindness; 2, to take action on establishing a Bureau of Public Health; 3, to petition the Legislature with reference to an improved plan for registering births and deaths.

The Committee on Legislation told of the hard work it had to do, in order to have the Legislature pass the bill creating a Board of Medical Examiners, and when it was announced that all the work had amounted to nothing because Governor Rich had seen fit to veto the measure, the news was received with hisses.

DR. DONALD MACLEAN, of Detroit, called the attention of the Society to the advisability of reverting to the old method of electing officers, by which nominations are made in open session.

The following amendment was adopted: To change Article v, Section 1, of the Constitution, so as to read: "To facil-

itate professional and scientific work, three Sections are established, namely: 1, Section on Medicine and Obstetrics; 2, Section on Surgery and Ophthalmology; 3, Section on Abdominal Surgery and Gynecology."

The amendment to add to Article II, of Section 1 of the Constitution, "Provided that no alien can become a member of this Society," was lost.

A committee of three was appointed to take into consideration the question of undertakers embalming bodies. The point aimed at is to see if some preservative aside from arsenic can not be employed.

PRESIDENT WALKER announced that it would be necessary for him to leave the city in a few hours, and asked permission to deliver his address, which was granted.

In his remarks he touched on general topics, and among other things he said: Should we make an inventory of the progress of medicine and surgery, we will find that the advance in our profession during the last fifty years is far beyond that of any previous half century. In fact, our authorities comprise but few men, while to-day the life of an authority is of short duration, for intense active criticism is such that no observation is accepted as true, until it has stood the test of crucial criticism. This progress is largely due to the aids that have been given us through the discovery of anesthetics and a more accurate knowledge of disease, thereby permitting the surgeon the greatest opportunity for exploration and the physician the widest field for experimentation with remedies. Sims, through the invention of his duck-bill speculum, and the employment of the silver wire suture made him master of a class of operations that had heretofore been failures. Speaking of silver wire as a suture, it is undoubtedly the best and safest owing to its being easily made aseptic. We notice that many surgeons are for this reason returning to its use. The introduction of anesthetics, such as nitrous oxid in 1844, ether in 1846, chloroform in 1847 and cocaine in 1859, made it possible for many operators rather than the few, such as flourished in the days when it was necessary to immobilize the patient with buckles, straps and other apparatus. Surgery had now entered upon a new era when greater care in detail of manipulation could be exercised rather than manual dexterity. Yet ideal surgery was not realized until the advent of antiseptics, due to the efforts of Pasteur through his studies of spontaneous generation, when after twenty years of investigation in 1878 he announced his results to the Paris Academy of Medicine; that which overthrew the doctrine of spontaneous generation, and established a pathology founded upon bacteriology. This study of bacteriology has opened a still wider field of investigation and made it necessary that we must have at least a thorough theoretical knowledge of the subject to appreciate its importance, while every progressive surgeon and physician must do practical work in the bacteriologic laboratory. Suppuration twenty-five years ago was the rule and meant a fight to the death of either the phagocyte or bacterium. Pus is dead phagocytes, the prevention of which is the aim of the surgeon; how well he does it is shown by results. Antisepsis and asepsis are too often a farce. Few but believe in its efficacy, yet how few accomplish it, simply from a failure to follow out every detail, for a weak link in a chain makes the whole worthless. The knowledge of the bacteriologist has made surgery what it is to-day, a nearly perfect art. All reverence to Pasteur and Lister!

How is it with the pathology of the internal organs? The toxins of the microorganisms producing typhoid fever, cholera, diphtheria, etc., are gradually becoming better understood and immunity by inoculation promises much. Jenner by accident gave us the first evidence of immunity which has been used empirically for nearly a century, and is now regarded as a scientific application of the principles of bacteriology. It is hardly necessary to measure the results by this method in the treatment of hydrophobia. We have not, however, been as successful with the uses of certain remedies against tuberculosis, yet much is promised by the nucleins. Serum-therapy evidently possesses great advantages in combating diphtheria; it has not, however, stood the test of crucial criticism as yet. This intense investigation has developed a large body of specialists who in many departments have done the great wonders of our profession. Yet with all due respect to the specialist I can not but feel the furore in some instances goes beyond its environment and has done much to injure true conservative surgery and medicine. A specialist is not made in a day. He should be the product of scientific evolution. The laxness of the laws governing the practice of medicine in this country is gradually disappearing.

The adoption by a great majority of the medical colleges

of the United States of a four years' graded course is another step in the proper direction, and a still further advance should be a more rigid entrance examination; a thorough scholastic training, a knowledge of biology, botany, chemistry and bacteriology should be a part of the requisites for entrance, and not a part of the curriculum of a medical college.

Recently I sent out a circular letter to all of the regular practitioners in this State outside of our own membership, inviting them to become members of the society. I have received many responses of promises to attend, and others who find it inconvenient to be here at this time, asking if it is not possible to become members upon application without being present. I would suggest that a resolution be offered at this meeting making it possible for a regular practitioner of this State to become a member by application on the recommendation of two members and referred to the Committee on Admissions, who should have power to pass upon their eligibility, notifying the Secretary of their action. In this way we would secure a larger membership and a larger attendance in the future.

"I have some hesitancy in presenting what I am about to do, that is in suggesting the doing away with our Section work. There are many attending these meetings who would like to hear all the papers read, for the general practitioner comes here for the purpose of absorbing as much medical and surgical knowledge as possible, which he can not do when the work is going on in different places at the same time. Make the session three days; the morning of the first day for general business reports of committees, etc., on the opening of the last day and the rest of the time devoted to scientific work. It gives the writer of a paper an opportunity to be heard by all and not by a corporal's guard as is often the case in our present plan of Section work. I am aware that there will be opposition by many to this proposition, yet I think the majority will agree with me.

Dr. Walker concluded by quoting Joaquin Miller's poem, "Down in the Dust."

#### FIRST DAY—AFTERNOON SESSION.

In the Section on Surgery, the following papers were read and discussed: A Plea for the Employment of an Almost Discarded Method of Treating Urethral Strictures, by Dr. C. B. Nancrede, of Ann Arbor; Treatment of Urethral Stricture, by Dr. E. T. Tappey, of Detroit; The Cystoscope and its Limitations as a Diagnostic Aid, by Dr. F. W. Robbins, of Detroit; Methods of Relief in Prostatic Obstruction, by Dr. Wm. N. Wishard, of Indianapolis, Ind.; Operations on the Prostate, by Dr. H. O. Walker, of Detroit.

Papers were read and discussed in the Section on Medicine as follows: The Etiology of Diphtheria, by Dr. F. G. Novy, of Ann Arbor; Its Diagnosis, by Dr. C. H. Johnston, of Grand Rapids; Treatment, General and Medicinal, by C. G. Jennings, of Detroit, and Treatment by Serum, by Dr. C. T. McClintock, of Ann Arbor.

In the Section on Midwifery and Gynecology, papers were read on Malignant Diseases of the Uterus, as follows: Pathology, by Dr. J. B. Whinery, of Grand Rapids; Etiology, by Dr. E. G. Minar, of Bay City; Diagnosis, by Dr. Eugene Boise, of Grand Rapids; Surgical Treatment, by Dr. J. H. Carstens, of Detroit. Palliative Treatment, by Dr. H. W. Longyear, of Detroit.

#### FIRST DAY—EVENING SESSION.

The evening session was presided over by Dr. Victor C. Vaughan. The session took the form of three addresses.

DR. SCHUYLER C. GRAVES, of Grand Rapids, after a pleasant introduction to his address

#### THE POETICAL IN SURGERY

said in part:

As to title, novelty will certainly be granted, because the laity, and, for that matter, many medical men and women as well, have never thought of any possible connection between the "ars poetica" and the "ars chirurgica."

Science is knowledge, nothing more or less. Art is the application of knowledge. Art is the ability to make manual application of the principles perceived by science. For instance—the knowledge that drainage is one of the greatest of the underlying surgical principles in science. The application of this principle to any individual case; that is, the securing of the conditions necessary for its operations, art, and the better this is done the more artistic the action.

Surgery, then, is a science and an art. As a science, however, surgery is purely professional; but as an art it passes beyond the professional and into the poetical. Inasmuch as poetry is an expression of the good, the true and the beautiful, surgery, if poetic, must, also, be a reflection of the same

attributes. Let us see. Surgery is good, because it relieves suffering and saves life. Surgery is true, because it falters never in the steadfastness of its purpose. Surgery is beautiful, because it exhibits results which are pleasing to the eye, and to the mind and heart as well.

To many people, thoughts of surgery are associated with such matters as pain and blood and pus, and tumors, and deformities, over which the bird of poesy's paradise does not seem to spread her irised wings; but these things do not constitute the sum total of surgery, and in the contemplation of our theme we must remember that such matters are, oftentimes, but the means to an end; oftentimes, the very stimuli to poetic effort. They are but the marble dust and clay on the floor of the sculptor's workshop; the daubings of color on the palette of the painter.

DR. C. B. BURR, of Flint, delivered the Address on Medicine. He selected for his subject,

#### SOME CURRENT ERRORS RESPECTING INSANITY.

He said it was a grave error to believe in harmless lunacy; that the existence of an insane delusion was a menace to the community's safety. Graveyards are recruited constantly through the conduct of the harmless cranks, sane on all subjects but one. He asked the question: "What marked kinship exists between genius and insanity?" and answered it thus: That geniuses become insane through too close application in some particular mental groove is possible, but I am indisposed to think that the existence of genius, properly so-called, is a menace to the person's well-being. If his inventive or his literary efforts occupy his entire working hours, interfering with his rest at night, prevent him from exercising and taking food at regular periods, the physical cause for insanity becomes operative. If he occupies himself in one line to the exclusion of every other diversion and mental exercise, his horizon will be apt to become contracted but this does not constitute insanity.

Great geniuses have usually been great brain workers, have frequently burned the nervous candle at both ends, have too often resorted to stimulants and opium to excite imaginative power, have led profligate and dissolute lives under the temptations and flattery with which they were surrounded, and have placed themselves under conditions which jeopardize the integrity of the nervous system.

That there is any legitimate relationship between genius and insanity, may be disputed. I have never in my experience discovered such connection.

I think there is a general error respecting the relative liability of brain workers and hand workers to insanity. As a matter of fact, hard manual labor appears to break down more men and women proportionately than brain work.

Another error is the belief that insanity is increasing to an alarming extent. That there is a relative increase in nervous diseases is probable. This is due to the absence of any legal restriction upon marriage and the unchecked propagation of the defective classes. I am inclined to the belief that diseases which the alienist is called upon to treat, display in recent years a greater tendency to assume organic forms. From this tendency which must operate to shorten life and diminish productivity it is perhaps safe to credit a diminution in the number of those nervous diseases in which heredity plays so important a part.

Dr. Burr, in closing, said that one of the greatest errors was the admission of inferior classes of foreigners who are permitted to become residents of the United States.

DR. W. H. YOUNG, of Nashville, read the

#### ANNUAL ADDRESS

of the Section on Midwifery and Gynecology. Among other things Dr. Young gave expression to the following views and ideas:

I hold that no person can be thoroughly equipped in gynecology whose mind has not been expanded by a general practice, sufficient to enable him to grasp the human system as a whole, and not merely as a part of it. Without such training, the specialist is liable to see and to interpret things in the dim light of his own limited sphere, and to forget that the human body consists of and contains more organs and performs more functions than is dreamed of in his philosophy.

To be a successful specialist, be that gynecic or whatever else it may be, requires that the mind and modes of reasoning be so fully developed that he may not be blinded to the fact that all headaches are not caused by errors of refraction, to be cured by the proper adjustment of the lenses, or that all pains in the head and back of the female are necessarily due to some organic or functional derangement of the generative organs.

## SECOND DAY—MORNING SESSION.

PRESIDENT WALKER called the general session to order. The following officers were elected:

President—Victor C. Vaughan, Ann Arbor.

First Vice-President—H. McColl, Lapeer.

Second Vice-President—R. W. Erwin, Bay City.

Third Vice-President—F. B. Tibbals, Detroit.

Fourth Vice-President—F. G. Novy, Ann Arbor.

Treasurer—William G. Henry, Detroit.

Secretary—C. H. Johnston, Grand Rapids.

Judicial Council—Henry B. Baker, Lansing; Francis A. Rutherford, Grand Rapids; Wm. T. Dodge, Big Rapids.

The officers of the sections are: on Medicine, Chairman, David F. Stowe, of Bay City; Secretary, A. P. Biddle, of Detroit; Orator, H. H. King, of Grand Rapids.

Surgery, Chairman, D. M. Greene, Grand Rapids; Secretary, A. F. Bulson, of Jackson; Orator, C. H. Baker, Bay City, Mich.

Gynecology, Chairman, F. G. Minor, Bay City; Secretary, J. B. Winnery, Grand Rapids; Orator, Reuben Peterson, Grand Rapids.

Mt. Clemens was chosen as the next place of meeting.

Under the head of "miscellaneous business" the Constitution relative to the election of President, Vice-President and Secretary was changed so that, hereafter, on the morning of the first day's session, the nominations for these offices are to be made in open session.

After the adjournment of the general session, the Sections reassembled, and the following papers in the Section on Surgery were read and discussed: Shock, W. S. Connery, Saginaw. Cataract—Simple Extraction—Report of One Hundred Cases, Eugene Smith, Detroit. Abdominal Nephrectomy, with Report of a Case, Reuben Peterson, Grand Rapids. Selected Cases of Railway Surgery, F. B. Tibbals, Detroit. Some Reflexes, with Cases to Illustrate, J. A. Porter, Brooklyn. Deafness; what are we doing to Prevent It? W. F. Strangways, Flint.

The Section on Medicine. The Public Care of Epileptics, by Colonization, W. M. Edwards, Kalamazoo. Friedreich's Ataxia, with Cases, Sidney I. Small, Saginaw. Some Forms of Tropic Neurosis, with an Illustration, W. J. Herdman, Ann Arbor. A Case of Insanity during Pregnancy, W. G. Henry, Detroit. Nuclein in Tuberculosis, with Report of Cases, H. M. King, Grand Rapids.

The Section on Midwifery and Gynecology gave the following papers: Retro-displacements of the Uterus, J. L. McLaren, Saginaw. Surgical Treatment of Ectopic Pregnancy, J. G. Lynds, Ann Arbor. Ectopic Pregnancy, Hugh McColl, Lapeer. Some Points Relative to the Use of Forceps, C. H. Johnston, Grand Rapids.

## SECOND DAY—AFTERNOON SESSION.

The reading of papers in the Section on Surgery was continued: Extraction of Biliary Calculus from the Common Duct, T. A. McGraw, Detroit. Reports of Interesting Cases, D. Milton Greene, Grand Rapids. Some Features of Strabismus, Leartus Connor, Detroit. An Analysis of Twenty-five Cases of Appendicitis, Schuyler C. Graves, Grand Rapids. Neuro-Retinitis with Special Reference to the Monocular Variety, A. E. Bulson, Jackson. Pathologic Lesions of the Inferior Maxillary Bone, with Report of a Case, E. B. Smith, Detroit. An Unusual Fatal Aural Case, Luke E. Schell and Don M. Campbell, Detroit.

The Section on Medicine read and discussed the following papers: A Case of Multiple Sarcoma, W. F. Breakey, Ann Arbor. The Present Management and Treatment of Croupous Pneumonia, D. S. Campbell, Detroit. Salicylic Acid in Pleurisy and other Diseases with Serous Effusion, George Dock, Ann Arbor. Rheumatism; Its Pathology and Modern Treatment, E. S. Pettyjohn, Alma. The Nervous Symptoms of Gout, David Inglis, Detroit. Personal Experiences Regarding Altitude in Organic Cardiac Disease, Hugh McColl, Lapeer.

The Section on Midwifery and Gynecology read and discussed these papers: Ultimate Results, Physical and Mental, in Gynecologic Operations, Eugene Boise, Grand Rapids. Menopausal Polysarcia Abdominalis, Walter P. Manton, Detroit. Vento-fixation of the Uterus, J. J. Mulheron, Detroit. The Status of the Buried Animal Suture and Ligation in Abdominal and Gynecic Surgery, H. W. Longyear, Detroit.

Blank Applications for membership in the Association at the JOURNAL office. Write for them; sent free.

## Medical Society of the State of Pennsylvania.

*Proceedings of the Forty-fifth Annual Meeting held at Chambersburg, Pa., May 21, 1895.*

[Special correspondence of the JOURNAL.]

(Continued from page 939.)

DR. KATE D. MIESSE of Easton, read a paper on "Nerve Muscle Atony in Girls."

DR. J. N. HUNSEBERGER of Skippack, a paper on "Aconitin in Neuralgia." He spoke of the treatment of the causes of the different neuralgias. The use of aconitin was briefly outlined, and he gave a short description of the physiologic action of this drug, and a report of his clinical experience with it.

DR. E. V. SWING of Coatesville, read a paper on "Rational Treatment of Fracture of the Femur near the Hip-joint in Aged Persons." The Doctor briefly related the history of eighteen cases of what is usually called "intra-capsular fracture femur," and advocated complete freedom in bed, on a cotton or hair mattress, without any attempt at extension and counter-extension, as giving almost the only promise of life, the old treatment being almost invariably followed by exhaustion and death.

At the afternoon session DR. L. H. TAYLOR of Wilkesbarre, read the

## ADDRESS IN OTOTOLOGY.

He referred briefly to the work of his predecessors, and then discussed the operation on the bones of the middle ear, quoting at some length the reports of Drs. S. MacCuen Smith, Grunert, Blake, Gomperz, Randall and others. He takes a conservative view of the operation and believes it should not be resorted to, until all proper remedial measures have first been tried. He thinks the operation in non-suppurative cases will soon be abandoned.

The work of the general practitioner in ear diseases should be in the line of prevention, i.e., such treatment of acute otitis media as will make subsequent operation unnecessary. He highly recommends early paracentesis of the membrane and thorough attention to cleanliness, with instillation of a few drops of a 4 per cent. solution of cocaine in Magendie's liquor morphine, to relieve pain. He also urged especial attention on the part of the general practitioner to treatment of catarrhal troubles of early life, as a means of preventing chronic deafness—the majority of such cases being caused by catarrh of the nose and throat.

The work of the rhinologist can not be separated from that of the otologist; operations on hypertrophied turbinates and deviated septa, to secure patency of the nasal passages, being an essential part of the treatment of chronic deafness. He uses Dench's apparatus for inflation of the Eustachian tube in preference to Politzer's air bag.

Mastoid disease was referred to briefly, recommending the general practitioner to perform Wilde's incision early rather than wait to send the patient to a specialist for opening of the mastoid. The address closed with a short discussion of foreign bodies in the ear.

DR. JOSEPH McFARLAND of Philadelphia, presented a paper on "Bacteriologic Examinations in Medicine or Surgery." He commented on the necessity for accurate systematic study of cases, not only by observation and physical examination, but also with the microscope and culture media, so that unexpected but likely important etiologic factors may be detected. He suggested the organization of laboratories by county and other medical societies, who shall buy and own the necessary apparatus, and delegate the work to some competent member who shall receive sufficient compensation to enable him to devote a necessary amount of time and labor to the work. The ideas contained in the paper refer more especially to the organizations in rural districts than to those in cities. For the establishment of the work, and its inception, reference can be made to the gentlemen who have offered their services to the State Society through Dr. Stevens, and who will gladly visit any society and tell them how to start and maintain a laboratory.

DR. JEAN SAYLOR-BROWN of Williamsport, read a paper on "Relief of some Cases of Functional Nerve Troubles by Curing Eye Strain." He gave a list of a few serious cases cured by relieving eye strain; notably, one of tic douloureux, several of diabetes, and one simulating Basedow's disease, with entire inability to walk, caused by injury to the brain.

DR. H. G. CHIRITZMAN of Chambersburg, presented a paper on "Faith and Therapeutics."

DR. H. M. ALEXANDER of Marietta, on "Vaccine Virus," showing the dangers of impure virus, the need of care in the culture of bovine virus, etc.

DR. H. A. ARNOLD of Ardmore, discussed the subject, "Whither are We Drifting?" He described the characteristics of the medical man in mediæval times, and again at a later period. He compared medicine and medical men of those times with the present. The present evil is the secret processes of manufacture, private formulæ, and the large space devoted to them in the medical journals. Is the practice of medicine soon to become nothing more than the means of finding a market for the wares of a host of unknowable medicine makers? Should the wholesale production of new "ines" and "antis" continue, and the flood of literature distributed through the mails be augmented? May it not be possible, in the near future, to discontinue the study of materia medica at our medical schools, and give the time to etiquette, society manners and other nice little things so necessary to attain prosperity?

DR. H. A. MOWERY of Marietta, on "Typhoid Fever."

DR. A. ENFIELD of Bedford, read an article on "Auto-Intoxication with Special Reference to Certain Diseases." He asserted that no germ can produce disease by itself. That the vitality and stamina or resisting power of man must first be broken down before a germ can effect entrance to the tissues. We do not always escape typhoid fever when we have pure water. The fact that the germ of typhoid fever has been found, does not prove that this germ is the pathogenic agent. We have found cases of typhoid fever developing long after all sources of possible infection have been removed. The development of disease is not due alone to chance meeting of man and microbe. No one pathogenic agent or condition is sufficient to produce disease. Man contains within himself the causes for most of his sickness. All diseases that have their origin in auto-intoxication can be controlled by the free administration of intestinal antiseptics.

DR. GEO. E. SHOEMAKER presented a paper on

#### VENTRO-FIXATION OF THE UTERUS.

Retroversion with descent of the ovaries or of the uterus is a prominent factor in a large number of chronic gynecologic cases. The condition is not fully described by the term retroversion, but is far from a simple one. Treatment confined to the perineum, if that is lacerated, to the endometritis or pelvic congestion, will produce no permanent change if adherent retroversion persists. The pessary can only be used when adhesions are absent, inflammation is slight and the organs capable of being thoroughly replaced. In a few cases, watched, it gives all the relief necessary. It cures only minor cases and these very seldom.

Practically, many cases apply from remote districts, or who are obliged to labor, or to whom months of rest with palliative treatment are out of the question, and then the surgeon's experience teaches that long-continued minor treatment will fail. Graver degrees of retroversion accompany conditions practically incurable without surgery. What shall it be?

The operation for shortening the round ligaments in the inguinal canals is limited to the cases without adhesions, and where the tubes and ovaries are known to be normal. These are not the most important cases. If thoroughly done it weakens the canal almost as much as a celiotomy weakens the abdominal wall.

Ventro-fixation is especially adapted to the adherent cases. Tubes and ovaries buried in inflammatory adhesions can be freed and treated. The bladder is not hampered greatly, as it widens in filling. Cases of the writer's hold six, eight or more ounces almost from the start. The attachment elongates into a muscular band which allows uterine and bladder movements. Pregnancy is not interfered with, except in probably increased vomiting and traction in early months. The band elongates and again shrinks.

Remote results in relieving symptoms are excellent in the writer's experience; but only cases should be chosen where the symptoms are due to the uterine condition. Minor retroversion may exist *per se* without symptoms.

Ventro-fixation is accessory to curetting and packing for endometritis, to perineal repair and other measures. Descent of the uterus below the pelvic outlet demands other treatment.

The method followed by the writer includes the buried silkworm gut suture through the rectus muscle and its sheath for the entire wound. The second and third sutures below include the fundus uteri. None of these sutures have ever required removal.

DR. S. MACCUE SMITH gave an interesting paper on

#### EMPHYEMA OF THE MASTOID AND ITS RELATION TO ACUTE AURAL DISEASE.

It was formerly taught that empyema of the mastoid could only occur as a complication of a *chronic* suppurative inflammation of the middle ear. While this is usually true, it is now conceded that this purulent invasion often occurs as the result of *acute* suppurative otitis media. This inflammation may arise either by direct continuity of structure, by infection through the venous circulation, or through the nutrient vessels which traverse the canaliculi and pass from the carotid canal to the mucous lining of the tympanic cavity. This extension of the inflammatory process may be prevented or promptly relieved, by intelligent action on the part of the attending physician.

Out of eleven cases of mastoid empyema, arising from acute otitis media, four showed only a superficial abscess, five were confined to the mastoid antrum, and two extended into the mastoid cells. In the four cases of superficial abscess the pus had burrowed its way through the thick outer walls in less than one month, and a Wilde's incision was sufficient to establish free drainage. In the remaining seven it was necessary to trephine the mastoid. It is difficult to account for the extensive destruction to the soft parts and to the dense bony walls, which may occur in a very brief period. It is also difficult to explain why the confined pus should burrow out through a very thick plate of bone, instead of penetrating through the thinner osseous wall that separates the mastoid and middle ear cavities from the interior of the skull.

The points to be noted are: 1, the fact that mastoid complications do frequently develop from *acute* inflammation of the middle ear; 2, the necessity for prompt recognition and relief of *acute* inflammatory disease of the ear; 3, immediate evacuation of pus when present.

DR. S. D. RISLEY read a brief paper on

#### OCULAR AFFECTIONS ASSOCIATED WITH LITHEMIA.

Disclaiming any purpose of discussing all the protean manifestations of the gouty or rheumatic dyscrasia, he pointed to the fact that many of the minor discomforts and affections of the eye found their *fons et origo* in fleeting and recurring attacks of lithemia in persons who have acquired the diathesis by sedentary habits, imprudence in diet, by chronic malarial poisoning, syphilis, etc., or are victims of hereditary liability. Fleeting attacks of conjunctivitis which not infrequently pass for catarrh of the conjunctiva, hyperemia of the uveal tract which may develop the milder forms of recurrent iritis, or even more violent attacks, are frequently due to this systemic condition, and not infrequently their essential nature passes unrecognized. Many patients with weak eyes and low grades of refractive error, receive correcting glasses for the relief of their tender eyeballs, periorbital neuralgias and occipital headache, when they might be spared the incubus of a pair of glasses, certainly for constant wear, if due attention had been given to this constitutional malady. Cases were briefly related to illustrate the various phases of the teaching. Unfortunately, its manifestations were not confined to these milder forms of eye disease, but were very frequently at the foundation of the most rebellious and fatal forms of ocular affections. The serious involvement of the general vascular tree, in the more advanced stages of lithemia, was mentioned briefly, and the great liability of the vessels of the choroid and retina to participate in the general disaster urgently insisted upon as of great importance in the study and treatment of many forms of eye disease, occurring during and after middle life, in patients afflicted with the gouty or rheumatic diathesis. It stood second only to syphilis in the etiology of iritic disease. The impairment of the nutrition of the eyeball consequent upon the disease of the choroidal and retinal vessels, rendered it especially liable to choroiditis, hemorrhagic retinitis, incipient cataract, and the more vicious forms of glaucoma. It was this state of the ocular circulation which not only was the origin of many cases of these perilous forms of disease, but which rendered them so fatal to vision and so slightly amenable to all purely local treatment. It was the frequency of such participation in general disease which made it necessary for the ophthalmic surgeon to be also a wise physician. There was no room, anywhere, for the specialist who divorces his special work from the broad field of medical science.

DR. J. K. YOUNG of Philadelphia, read a paper on "Massage in Surgery," in which he reached the following conclusions:

1. Massage as an adjunct in the treatment of surgical disease is apt to be overlooked by the surgeon.

2. Its field of application is very large, including the diseases of the joints, traumatism, after operations, and diseases of the nervous system.

3. Its mode of application differs in the different conditions, and must be understood to obtain the best results.

4. The advantages to be gained by its more frequent use are more rapid and complete recovery from surgical disease.

Dr. E. E. MONTGOMERY, of Philadelphia presented the subject "When should Vaginal be Preferred to Abdominal Incision in the Treatment of Pelvic Disease?" Dr. Montgomery advocated vaginal incision in all collections of pus in the pelvis which could be readily reached through the vagina, and said that this method of treatment in the majority of cases afforded a decreased danger to the patient and an opportunity for recovery without sacrifice of important organs. Its practice does not add to the danger of an abdominal operation if the latter is necessary for the cure of the patient. Where the uterus is the source of infection, as in puerperal sepsis, and the sacrifice of the tubes and ovaries is indicated, he would also extirpate the uterus and do the operation per vaginam.

Dr. CHARLES P. NOBLE, of Philadelphia, read a paper upon the subject of

#### MOVABLE KIDNEY,

and the following are his conclusions: Movable kidney is a very common condition among women. I find it in one-fourth of my own patients. Both kidneys are movable in about one-tenth of the cases. The underlying cause of movable kidney is a deficiency of adipose tissue, especially in the peri-renal region. Tight lacing, multiple pregnancies and falls, occasionally act as contributing causes. The symptoms of movable kidney are both reflex and local. The reflex symptoms are those, at times, of neurasthenia, irrespective of its cause. In other cases, nervous dyspepsia, palpitation of the heart; distension of the abdomen with gas and neuralgic areas are the symptoms complained of. Patients usually are unable to lie upon the side opposite to the movable kidney. The local symptoms are a sense of weight or bearing down, soreness in the kidney region, attacks of pain similar to renal colic, and in rare instances symptoms of strangulation due to torsion of the vessels of the kidney.

Movable kidney may be suspected when its rational symptoms are present, but the diagnosis must be made by a physical exploration. This should be made with the patient in a standing position. The diagnosis can be made with the patient lying on her back only in long standing cases, where the displacement is extreme, as usually in this position the kidney slips up under the margin of the ribs. In many cases movable kidney gives rise to no symptoms, and therefore does not require treatment. The rest cure promises to be efficient in cases of slight degree, as the kidney returns to its normal position while the patient is lying on her back, and the increasing fat which the rest cure usually brings about should effect a cure. The rest cure used in cases of long standing, with extreme displacement of the kidney, will improve the general condition of the patient but will not improve the local trouble. Nephrorrhaphy is a simple and safe operation, which should be done in the cases having well-marked displacement, that is three inches and upward. The more marked the local symptoms the more necessary the operation. The reported cases indicate that the results are permanent.

One object of this paper is to emphasize the great frequency of this condition, and the ease with which it can be diagnosed. Also, to urge upon those who have not done so, the necessity for studying its relation with the various reflex and nervous symptoms met with in thin women.

Dr. LOUIS J. LAUTENBACH, of Philadelphia, read a paper on

#### DEAF MUTES—CAN THEY BE MADE TO HEAR?

During the past sixteen months the Doctor has had under treatment six deaf mutes. All of these he has treated by massage methods—phono, pneumo and mixed massage. In all there has been some improvement in hearing; in three the improvement has been very noticeable. From the study of these cases he has derived the following conclusions:

1. That no negative opinion as to the results of treatment can be considered as justified, even when all our ear tests fail to indicate the slightest trace of hearing power.

2. That every deaf mute should have his ears thoroughly examined, the proper treatment instituted, and that this treatment should consist not only of former methods but should include pneumo, phono and mixed massage treatment.

3. That as a result of this method of treatment, favorable effects have been obtained which have not been realized by any former treatment.

4. That in the present status of our knowledge, we know not to what extent the power of hearing may be developed by this method; the lack being occasioned by the need of a greater period of time to allow of the further development of the hearing function.

5. That even though the hearing of deaf mutes be not restored to normal or anywhere near thereto, yet the hearing powers as developed during the comparatively short period that this method of treatment has been in use, would prove of great value to the deaf mute, not only in the development of his speech functions and in the protection of his person from external injury, but would be of great value to his family and friends in their more ready communication with him.

6. That through the improvement by the massage treatment the teaching of deaf mutes of the lip-reading method and the utterance of sounds in accordance with it, this teaching can be more readily accomplished and more deaf mutes thus be given the advantages of such education.

On motion, the Committee of Publication were given discretionary power to issue the proceedings in journal form.

On motion of Dr. BENJAMIN LEE, of Philadelphia, it was unanimously

*Resolved*, That the Medical Society of the State of Pennsylvania believes that the time has arrived when questions of public health should be decided and administered by an authority at the National Capital, constituted for that purpose solely; and therefore urges upon the representatives of the State, in the Congress of the United States, the importance of sustaining the movement already inaugurated for the establishment of a Department of Health at Washington.

On motion of Dr. I. C. GABLE, of York, it was resolved that this society respectfully suggests to the State Board of Health that the sanitary condition of the establishments for propagating vaccine virus should be subjected to frequent inspection; that we will be ready to cooperate with the board in any measures which may be necessary to provide for such action.

On motion of Dr. S. S. TOWLER, of Marienville, it was

*Resolved*, That the Medical Society of the State of Pennsylvania congratulates the AMERICAN MEDICAL ASSOCIATION upon the decision of the Trustees to exclude unethical advertisements from the JOURNAL of the ASSOCIATION.

*Resolved*, That a committee of three be appointed to communicate with the editors of the medical journals of the United States, calling their attention to this action of the JOURNAL of the ASSOCIATION, and requesting them to accede to the wishes of the profession by adopting a similar rule.

Committee—Drs. Towler, C. H. Thomas, of Philadelphia, J. J. Buchanan, of Pittsburgh.

A resolution indorsing the idea of the individual communion cup was laid on the table.

On motion of Dr. H. B. GUTHER, it was

*Resolved*, That the Committee on Pharmacy request of the Pharmaceutical Society of Pennsylvania to transmit the constituents, etc., of the newer preparations for publication in our Transactions, etc.

On motion of Dr. J. A. EHLER, of Lancaster, the Secretary, Dr. Atkinson, was requested to prepare a History of the State Medical Society and present it at the annual session of 1896.

Resolutions of thanks were adopted to the ladies, the Committee of Arrangements, the Franklin County Medical Society and the officers of this body for what has been done to make this one of the most successful and enjoyable ever held.

The society assembled May 24, and formally installed the newly elected officers, after which it adjourned to meet in Harrisburg, the third Tuesday in May, 1896.

#### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine  
New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

(Continued from page 898.)

#### THE INCANDESCENT ELECTRIC LIGHT, OR RADIANT HEAT BATH.

This paper was read by Dr. J. H. KELLOGG, of Battle Creek, Mich.

Almost since the discovery of the electric light, it has been

made the subject of interesting experimentation for the purpose of discovering whether this excellent artificial substitute for sunlight possessed the property of stimulating the vital processes of plant life in a manner analogous to the action of sunlight. An interesting paper, by Wm. Siemens, published in March, 1880, contained a detailed account of experiments made for the purpose of determining the influence of the electric light upon vegetation, and from which the following conclusions were drawn by the author:

1. That the electric light is efficacious in producing chlorophyll in the leaves of plants, and in promoting growth.

2. That an electric center of light, equal to 1,400 candles, placed at a distance of 2 meters from growing plants, appeared to be equal in effect to average daylight at this season of the year (March), but that more economical effects can be attained by more powerful light centers.

3. That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc, produce no sensible deleterious effects upon plants inclosed in the same space.

4. That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during the daytime to sunlight and during the night to electric light.

5. That the radiation of heat from powerful electric arcs can be made available to counteract the effect of night frosts, and is likely to promote the setting and ripening of fruit in the open air.

6. That while under the influence of electric light, plants can sustain increased stove heat without collapsing, a circumstance favorable to forcing by electric light.

Similar experiments have been made by others. The first to make experiments was Hervé-Mangon (Compt. Rend. 53, 243). These experiments showed that the electric light was capable of causing the development of chlorophyll and inducing heliotropism, or the phenomenon of turning or bending towards the light.

Prillieux (Compt. Rend. 69, 410) showed in 1869, that the electric light is capable of promoting assimilation of plants, or decomposition of carbon dioxide and water.

Siemens found that the plants exposed to ordinary daylight and six hours of electric light in addition "far surpassed the others in darkness of green and vigorous appearance generally." Strawberries and other fruits were fully equal to those raised under ordinary conditions, and grapes were of stronger flavor than usual. Melons were remarkably large and aromatic, and bananas were pronounced by excellent judges to be "unsurpassed in flavor."

Many of these experiments have been repeated in this country and with similar results. The most important experiments were those conducted at the Cornell University Agricultural Station in 1889-90. These results showed clearly:

1. That the electric light may be used under such conditions as to make it fairly comparable to sunlight in its power to promote protoplasmic activity.

2. That the electric light acts as a tonic to plants so that they are able to endure adverse conditions which otherwise would cause them to collapse.

3. That the electric light is a true vital stimulus, since the effect of its use at night, upon plants, is essentially the same as that of the longer day of the Arctic upon plants growing in that region.

Another fact of importance which had sometimes been observed, was the deleterious influence of powerful arc lights upon workmen engaged in close proximity to them, effects analogous to those of sunstroke.

Although not fully acquainted with the facts above referred to, when I first began the use of the electric light bath, I had seen brief notices of these experiments, and thereby became interested in the subject from a therapeutic standpoint. For more than twenty years I have made use of the sun-bath as a therapeutic means, and twelve or thirteen years ago experimented with large convex lenses for the purpose of concentrating the sunlight, and thus intensifying its effects in the treatment of neuralgia, spinal and other hyperesthesias. I found good results from its use employed in this way, but did not complete my observations on account of the great amount of time required and the uncertainty of having sunlight at the time desired.

Something more than four years ago I began experiments with single lights provided with reflectors, and soon after I had constructed two cabinets, or small rooms, large enough to contain one person, and arranged in regular rows on the inside 50-60 incandescent lamps. Since that time I have made constant use of the electric light emitted by the in-

candescent lamp, as a therapeutic means. Together with my colleagues I have employed the bath by this means nearly ten thousand times, and in a great variety of ailments, at the Battle Creek Sanitarium, and have largely used it as a substitute for the Turkish, Russian, vapor, and hot-air baths, all of which I had previously employed for many years. Finding it free from any of the objections to which the baths named are open, for numerous reasons, some of which I will point out subsequently in this paper, and also finding its effects extremely agreeable to patients, and remarkably efficacious in many stubborn cases which did not readily yield to other therapeutic agents, I have employed it much more frequently than I had previously made use of analogous means, and in a much wider range of cases.

My earliest experiments in the use of the electric light bath showed me that it was capable of producing very characteristic effects. This led me to undertake a series of physiologic experiments for the purpose of placing its therapeutic use upon a rational basis, and for the purpose of comparing the effects of the electric light, Turkish, and Russian baths. Some of these experiments were made three years ago; others have been made more recently. The objects of the experiments were to determine the effects of the electric light bath as compared with those of the Turkish and the Russian baths upon:

1. CO<sub>2</sub> elimination.
2. The urea secretion.
3. Perspiration.
4. Surface and internal temperature.

5. The number of blood corpuscles and the amount of hemoglobin. The results of these experiments and the methods employed may be summarized as follows:

1. *CO<sub>2</sub> Elimination.*—Three healthy young men were subjected to the influence of the incandescent electric light or radiant heat bath for five, ten, twenty, and thirty minutes respectively, the time being the same for each, and all other conditions being made as near alike as possible. The same young men were likewise subjected to the influence of the Turkish and the Russian baths for the same lengths of time, but on different days, care being taken to maintain a uniform dietary during the entire series of experiments, at the same hours of the day. The influence of the bath upon CO<sub>2</sub> elimination was determined by carefully measuring with a delicate air meter which I had constructed for the purpose, all the air expired during the ten minutes before the experiment, collecting an average sample of the air for analysis. During the bath the air was collected for the same length of time. In a case in which the bath lasted only five minutes, the figures were doubled so as to make them comparable with the rest. In case the bath continued twenty minutes or more, the air was measured and collected during the last ten minutes; the results obtained were corrected for barometric pressure and vapor tension so that the figures given in the table for the different experiments are, in every respect, properly comparable. The results were as follows:

The average per cent. of CO<sub>2</sub> obtained before the experiment was 3.60.

For the electric light bath the average per cents. obtained were as follows:

5 minutes	4.10
10 "	4.10
20 "	4.20
30 "	5.10 and 5.13

In a repetition of the thirty-minute bath, the higher percentage of 5.13 was obtained.

For the Turkish bath the average per cents. obtained were:

5 minutes	4.03
10 "	4.07
30 "	4.01

For the Russian bath the per cent. was 3.96 for a bath of thirty minutes.

The highest amount of CO<sub>2</sub> elimination was 4.20 liters, which was in the incandescent electric light bath for thirty minutes.

The temperatures of the air in the baths were as follows: Electric light bath, 28 to 36 degrees C. (85 to 97 degrees F.), or constantly below the temperature of the body; Russian bath, 38 degrees C. (100 degrees F.); Turkish bath, 55 degrees C. (131-155 degrees F.).

2. *Urine Secretion.*—The following table shows the average figures obtained for the three young men who were the subjects of experiment. The facts determined in relation to the urine were: the amount of specific gravity, the acidity, the amount of urea, the amount of uric acid, the total chlo-

rids expressed in terms HCl, the phosphoric acid and the total solids. The figures given were determined by accurate quantitative analysis of the whole amount secreted in twenty-four hours. The figures obtained in relation to the most important of these quantities were as follows:

Electric light bath: Urea . . . . .	26.32 gms.
Total chlorids . . . . .	5.25 "
Total solids . . . . .	49.30 "
Turkish bath: Urea . . . . .	27.39 "
Total chlorids . . . . .	6.91 "
Total solids . . . . .	52.70 "
Russian bath: Urea . . . . .	29.56 "
Total chlorids . . . . .	7.60 "
Total solids . . . . .	55.14 "

The figures obtained for the urine were the exact reverse of those obtained for the CO<sub>2</sub> elimination.

3. *Perspiration*.—Two points were determined in reference to perspiration:

1. The time required to induce perspiration.
2. The temperature at which perspiration began.

The averages were as follows:

Incandescent electric light bath: time required to induce perspiration, three minutes, thirty-two seconds. The average temperature at which perspiration appeared was 27.2 degrees C. (81 degrees F.).

Turkish bath: the time required to induce perspiration, five minutes, thirty-five seconds. Temperature of the bath, 53.6 degrees C. (128.5 degrees F.).

Russian bath: the time required for perspiration, six minutes, forty-five seconds. Temperature, 101.8 degrees F.

The above figures show very clearly the superior value of the electric light bath as a means of stimulating cutaneous activity.

4. *Surface and Internal Temperature*.—The influence of the bath upon surface and internal temperatures is a matter of importance, since Bouchard has shown that the heat regulating apparatus of the body is called into operation by a rise in the temperature of the blood equal to 40 degrees C. (104 degrees F.).

In experiments made in December, 1891, for the purpose of determining the effect of the bath upon surface and internal temperature, I obtained the following results in a comparative study of the effects of the electric bath and the Turkish bath upon surface and internal temperature.

Electric light bath: temperature of bath, 34.5 degrees C. (94 degrees F.). Internal temperature of subject before the bath, 36.6 degrees C. (98 degrees F.). Surface temperature 35 degrees C. (95.44 degrees F.). Patient began to perspire after one minute. At the end of five and a half minutes he was removed from the bath. The temperature was taken at once and the internal temperature was found to be 37.5 degrees C. (99.6 degrees F.); the surface temperature, 37.9 degrees C. (100.2 degrees F.). Ten minutes after the bath the mouth temperature was 37 degrees C. (98.5 degrees F.); and the axillary temperature was 36.6 degrees C. (98 degrees F.).

Turkish bath: temperature of bath, 70.5 degrees C. (159 degrees F.). Temperature of the subject before the bath 36.4 degrees C. (97.4 degrees F.); axillary temperature 96 degrees F. Perspiration began in five and a half minutes. Immediately after the bath, the mouth temperature was found to be 37 degrees C. (98.7 degrees F.); axillary temperature, 37.2 degrees C. (99 degrees F.). Ten minutes later the mouth temperature was 37 degrees C. (98.8 degrees F.); axillary temperature, 36.6 degrees C. (98 degrees F.).

From these statements it appears that the incandescent electric light bath is far more effective than the Turkish bath in raising both surface and internal temperature, which clearly indicates the penetrative power of the intense heat rays of the electric light.

5. *The Blood*.—The effects of the incandescent electric light bath upon the blood were determined by a careful count of the corpuscles by Gower's instruments and a determination of the hemoglobin by the hematoscope of Henoek. The figures obtained showed no very marked increase in either blood corpuscles or hemoglobin, although in one case the number of corpuscles was increased nearly 200,000 per cubic mm.

The physiologic effects of the electric light bath are chiefly those of heat, and do not differ very essentially from the effects obtained from other sources of heat, except that the electric light bath is a much more efficient and convenient method of administering heat than any other which has been devised, with the exception of water, which doubtless has a wider range of use.

The purposes for which heat is applied are usually two:

FIG. 1.—Electric Light Foot and Leg Bath, and Spine Bath.

FIG. 2.—Electric Light Trunk Bath.

The diminished amount of urea, total chlorids and total solids present in the urine during the twenty-four hours to which the subject was subjected to the electric light bath was evidently the result of increased elimination by the skin, showing that the electric light bath is much more powerful than either the Turkish or Russian bath as a means of stimulating vicarious eliminative work upon the part of the skin.

The amount of perspiration induced by the incandescent electric light bath was fully double that induced by the Turkish bath in the same length of time.

The amount of perspiration induced by the Russian bath was even less than that induced by the electric light and the Turkish bath.

## 1. The induction of perspiration.

2. The stimulation of protoplasmic activity, and thus increasing tissue metamorphosis. As before remarked, Bouchard has shown that a rise of temperature of .40 degrees C. (.17 degrees F.) is sufficient to induce perspiration. This rise of temperature may be produced either by artificial heat, by the retention of bodily heat, through diminished heat elimination, or by increased production of heat through exercise or other means.

In the Turkish bath a high temperature of the surrounding atmosphere and a considerable amount of time is required for the induction of perspiration, for the reason that the heat of the air is slowly communicated to the body and the heating of the skin and, through it, the transmission of heat to the blood is directly antagonized by the rapid evaporation produced by exposure to a dry atmosphere whereby the skin is rapidly cooled. This cooling may take place so rapidly, indeed, that a temperature of 500 or 600 degrees F. may be tolerated for a short period without injury, as was illustrated by the Fire King who used to enter an oven with a piece of raw beef and remain until it was roasted.

In the incandescent electric light bath the heat enters the body directly as a radiant force, instead of by the slow method of convection and conduction, thus more rapidly raising the temperature of the blood, and hence quickly inducing perspiration. That heat stimulates vital activity is a fact with which every one who has ever studied the amoeba or white blood corpuscle upon the warming stage is well acquainted. The effect of poultices and fomentations in producing pigmentation of the skin, as well as the effects of

atmosphere, and hence is easily and instantly controllable.

The instant the lamp is turned off, the heat which it has previously emitted is withdrawn from operation. If additional heat is required, the desired number of lamps may be turned on and become instantly operative.

Another reason for the more universal application of the incandescent electric light bath is the fact that when properly applied, its effects are highly tonic in character. A short application of the bath at full force for a time just sufficient to induce powerful stimulation of the skin without provoking perspiration is one of the most effective means of peripheral stimulation with which I am acquainted. The tonic effects of such an application may be still further intensified by instantly following the bath with a cold spray or other cold application, thus producing a revulsive effect of the most agreeable and effective character. The excessive heating of the skin prepares the way for the cold application, without at the same time so overheating and relaxing the blood vessels as to render recovery of the tone of the cutaneous tissues so tardy as to involve the risk of exhausting the patient too greatly or exposing him to the liability of taking cold.

The advantages of the incandescent electric light over the

FIG. 3.—Electric Light Trunk Bath, in use.

intense heat, either from the sun or other incandescent sources upon the complexion, afford further evidences of this important physiologic effect of the heat. Entering the body directly instead of slowly working its way through the poor conductors which are found in the successive layers of tissues which compose the covering of the body, the radiant heat of the incandescent electric light, stimulates and vitalizes the tissues to a high degree.

*Therapeutic Uses.*—I have found the electric light bath of far greater value in the treatment of a great variety of maladies than any other means of applying heat except water, and find that it may be much more generally employed than the ordinary Turkish, Russian, vapor, or hot air baths. One reason of this is the convenience and rapidity with which the degree of heat employed may be graduated by turning on or off one or more groups of lamps, by which means the amount of heat is rendered absolutely and instantly controllable. The source of heat relied upon is the incandescent filaments of the lamps rather than a heated

FIG. 4.—Upright Cabinet Electric Light Bath.

arc light for therapeutic applications are:

1. Its superior convenience in application and distribution in the bath.

2. Freedom from the deleterious effects which several observers have noted as due to the arc light when in too close proximity to plants, or when nearer than 2 meters. These effects were found to be not due to the gases given off by the lamp, but to some effect from the light itself. It can not be doubted that similar deleterious effects might follow the use of the arc light when applied for therapeutic purposes if placed nearer to the patient than six feet, a fact which must render its use inconvenient, if not dangerous, to say nothing of the impossibility of securing a uniform distribution in its application.

Still another especial advantage of the incandescent electric light bath over other sources of heat is the facility with which it can be localized. In this respect it is far superior to fomentations or any other local applications. By means of suitable appliances, the heat can be focused upon a small

point if desired, and affects not only the surface, but the deeper tissues. I am sure that the radiant energies of the electric light penetrate these tissues to a depth of several inches. This I proved by actual observation, as before intimated. For deep-seated pain, as well as for the relief of hyperesthesias of the skin, I know of no remedy more valuable. Many applications of this sort have been made by myself and my colleague, more than a thousand in all, and I have constant reason to be grateful for the acquisition of this therapeutic measure, as it has afforded relief to many cases which have stubbornly resisted all other therapeutic means which I have been able to employ.

I append to this paper a report of a number of cases treated by myself and my colleagues at the Battle Creek Sanitarium by means of the incandescent electric light bath and local applications of light, which are simply illustrative of hundreds of similar character which might be given.

*Rationale of the Effects of the Incandescent Electric Light Bath.*  
—The peculiar value of the electric light bath I consider due to its efficiency as a source of radiant energy. In the Turkish bath, heat is communicated to the body chiefly by the

ing the hand between an electric light and the eye, with the fingers in close contact; the hand being placed near enough to the light, the whole finger will be seen to be illuminated by the light, and not simply the soft parts.

It may thus be said that heat from the electric light penetrates the body just as it would penetrate any other transparent or semi-transparent medium, while the heat of the Turkish, vapor or Russian bath is communicated to the body by convection and slowly works its way into the body by heating the successive layers of living tissue which, although like glass, transparent to radiant energy, also possess to a greater or less degree the non-conducting powers of glass and allied substances. It is true that non-luminous as well as luminous heat waves are thrown off by heated bodies. The whole gamut of radiant energy in the form of heat being stated to consist of fully four octaves, more than two of which are below the red, while a whole octave is above the violet, the luminous range occupying a space only a trifle greater than what would correspond to the chord of the sixth in music. But the lower octaves of these heat waves seem to be far less active than those included within the luminous area and above it. I do not consider that there is any specific effect obtainable from the electric light which would not be derived from any equally efficient source of radiant heat, and on this account I have preferred the term, the *radiant heat bath* rather than *electric light bath*, as the former term leaves room for the employment of any other luminous source of heat, which must possess properties identical with those of the electric light.

One of the great advantages of radiant heat or incandescent electric light bath of the Turkish Russian, vapor, or similar form of bath, is the fact that the body can be subjected to the most intense heat desired without confining the patient, and without overheating the atmosphere surrounding him. This is due to the well-known fact that rays of heat pass through such transparent media as the air without heating them. This accounts for the intense cold experienced by balloonists, and by those who ascend high mountains, even in the tropics. The wood-chopper in the logging camp roasts his back before a big log fire on a cold winter's day, while Jack Frost is taking sharp nips at his nose on the other side. So the man in the incandescent light bath, while perspiring freely, may be surrounded by an atmosphere considerably below the temperature of the body, as shown in my experiments and in the daily application of the bath.

The question of priority in the use of the electric light bath is one in which I am not especially interested, but so far as I know, an empiric in Cincinnati was the first to make use of the arc light for therapeutic purposes. His use of the bath, however, was in connection with the "blue glass" fanaticism which spread so extensively over the country a few years ago, the electric light being substituted for sunlight, a very uncertain quantity at some seasons of the year. His use of the bath was, however, not founded on a scientific basis, and I have always regarded it as unworthy of thought or attention. About four years ago one of my colleagues, Dr. Kate Lindsay, called my attention to the personal benefit derived from the use of the heat of the electric light obtained by the application of a lamp in contact with the body and covered in such a way as to collect and retain the heat derived from it. I learned from several other persons of similar effects obtained in the same way and had constructed a variety of devices for applying heat at once to the different parts of the body, and also had constructed means for general application.

The first bath for general application consisted of a bank of lights, between thirty and forty in number, arranged upon a frame which was hinged upon the wall in such a way that it could be raised and folded back against the wall while the patient was placed upon a suitable couch beneath it. The patient being in readiness, the frame was lowered to a position about six inches above the body of the patient, and the space about the patient inclosed by means of curtains which dropped from the edge of the frame carrying the lights.

The second form of bath which I had constructed soon after, consisted of a cabinet about eight feet in height, (Figs. 4 and 5) upon the inside of which were placed between fifty and sixty incandescent lights arranged in rows, the spaces between the rows of lights being filled with silvered glass so as to multiply the number of lights to an infinite number by reflection. The cabinet is so arranged that the whole body of the patient, including the head, can be exposed to the influence of the light, or the head can be excluded, as in the ordinary vapor bath. The cabinet is freely ventilated, and by means

FIG. 5.—Cabinet Electric Light Bath, in use, head excluded.

convection of heat and air. Air being a very poor conductor, communicates heat to the body very slowly. Absorption of heat is further hindered by the skin, an excellent non-conductor, and by the rapid evaporation of moisture upon the skin, whereby it is cooled so rapidly that it is impossible for a man to enter and remain for a considerable time in an atmosphere far above the boiling point. I have several times been in a Turkish bath at 300 degrees and suffered no inconvenience. The heat is derived from the electric light, however, by radiation, and not by convection. The skin, as well as the air, is to a large extent transparent to radiant heat, and the same is true of all the living tissues. This is evidenced by the phenomenon of transillumination. By a speculum placed in the vagina or rectum and a suitably arranged electric light of 16 or 32 candle placed over the abdomen, it will be seen that the whole interior of the trunk is illuminated and made to glow with a bright red light, the red color being due to the reflection from the red corpuscles of the blood. Even the bones are transparent to light when in a living state. This is clearly shown by plac-

of switches and a proper grouping of the lamps in wiring, the number of lights in use can be instantly and perfectly controlled. This bath, which I have had in use for more than three years, is somewhat imperfectly shown in a photograph that I herewith present. A description of this bath was published in a German medical journal by Dr. Gebhardt, who visited the Sanitarium and personally tested the bath something more than a year ago.

The third form of bath for general application of the incandescent light, which I have had constructed more recently, consists of a cabinet lined with mirrors (Fig. 6) and containing some sixty incandescent lights, so arranged that the patient lies in a horizontal position, the lights being placed on three sides. The patient lies upon a suitable couch with rollers, which is pushed entirely within the cabinet, or only so far as to expose such portions of the body as it is desired to bring under the influence of the radiant light and heat. By this plan the influence of the light can be confined to the feet and legs, or any other portion of the body up to the neck. It is only necessary to protect, by a sheet and a piece of mackintosh, any portion of the body which it is desired to exclude from the action of the bath.

I have also had constructed and have in use special appliances by means of which applications may be conveniently made to the spine, the trunk, the feet, and other parts of the body.

enced the effect of one of these electric light baths. In his own case, it was difficult with drugs to produce diaphoresis. He had been warned that the electric light bath produced diaphoresis at a lower temperature than a Turkish or a Russian bath, and he had only been in the bath for a very short time before he realized the truth of this statement. The sensation was decidedly pleasurable and very restful. The head of the person was not exposed directly to the full light. He was thoroughly convinced by this experience that the electric light did really produce diaphoresis at a lower temperature than the other baths.

DR. MORTON said he was very glad that Dr. Kellogg had brought this subject before the Association. We should all follow it up more carefully than heretofore. He wished to congratulate the author on his methods of study—his physiologic experiments—as it was in just this way in the study of the ashes of the human machine that we could get the information which we so greatly desired. He had himself used the electric light as a local bath for a number of years—that is, a single portable incandescent lamp wrapped in a wet towel and used as a poultice. He had found it a very useful means of applying moist heat to patients in our mod-

FIG. 6.—Horizontal Cabinet Electric Light Bath.

After nearly four years' use of the electric light bath in a great variety of ailments, I esteem it as of greater utility than any other means of applying heat to the body, with the exception of water, the universal applicability of which gives it paramount value over all other therapeutic agents which can be employed for this purpose.

In conclusion, I wish to acknowledge my indebtedness to Professor Gomberg, of the University of Michigan, who kindly consented to devote a part of his vacation to the tedious chemic work required by this investigation, and to my assistants, Drs. Rand and Paulsen, who assisted in the chemic work, and carried out the details of the experiments with great painstaking, and to Dr. Burleigh for careful studies of the blood in connection with the experiments.

#### DISCUSSION.

THE PRESIDENT said he was satisfied that in the therapeutics of light we are going to have very rich results.

DR. MASSEY asked what the effect had been when the application had been made to the whole body.

DR. KELLOGG answered that he had found that when applied locally, with a powerful light, it tanned the skin.

DR. DICKSON said that after the last meeting he had visited Dr. Kellogg's Sanitarium, and had personally experi-

ern hotels. He had hoped to hear that there were effects from the electric light apart from the heating effects.

DR. GOELET asked what the effect of the light was upon the eyes.

DR. KELLOGG replied that the patient either closed the eyes or they were protected by a screen. The differences in the electric light bath from the Turkish and Russian baths might be attributed to the light, if one so desired. His statement on this point was purely theoretical, and it was quite possible that the very marked difference in the effect of the electric light bath might be due to the light and not to the heat. The quantity of perspiration was increased to double that by the Turkish bath for the same time. It was also noticeable that the surface temperature was higher than in the Turkish bath. The heating effects of the spectrum were included in a whole gamut of four octaves, whereas the light effects were in a comparatively small area. The blue and red rays were very active, as were also those above the visible end of the spectrum. The non-luminous rays below the red and above the violet were capable of producing photographs; and hence the therapeutic effects appeared to be due, not to the light but to the heat—at any rate, heat was a larger term and included light.

The Association adjourned at 6:15 P.M.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JUNE 22, 1895.

SEWAGE DISPOSAL ALONG THE GREAT LAKES.

In the report of the Chicago Health Department for 1894, recently issued, appears a tabulation of the claimed populations, reported deaths, and annual death rates per thousand, based thereon, of the sixteen cities of the United States having more than 200,000 inhabitants each. These embrace, in the order of lowest death rates per thousand of population, the following cities: Chicago, 15.24; Detroit, 15.49; Milwaukee, 15.71; Cleveland, 15.86; St. Louis, 16.13; Buffalo, 16.76; Pittsburg, 18.17; Philadelphia, 18.28; Cincinnati, 18.29; San Francisco, 18.85; Baltimore, 19.11; Brooklyn, 20.14; Washington, 20.23; New York, 21.03; Boston, 22.99; and New Orleans, 24.88.

The striking feature of this table is the group of cities lying on the shores of the Great Lakes—Chicago, Milwaukee, Detroit, Cleveland and Buffalo. The aggregate claimed population of the total sixteen cities is 9,934,058 and the aggregate of reported deaths is 185,632—an average mortality of 18.68 per thousand of population. But the five Great Lakes cities enumerated, with an aggregate population of 2,752,727, or nearly 28 per cent. of the total, reported only 42,830 deaths in 1894, which would give a mortality rate of 15.56 per thousand. This is nearly 22 per cent. less than the death rate of the remaining eleven cities, which is 19.88 per thousand. Without discussing at this time the credibility of these figures, it may be noted in passing that their compiler obviously anticipates that they will be challenged, and so says:

"An urban death rate and especially a Chicago death rate of less than 18 per thousand has been pro-

nounced incredible by the highest statistical authority in the country, and it remains to be seen what the reply will now be to what Virchow would call the 'brute force' of these aggregate figures. The only recourse seems to be to charge the five Lake cities with a conspiracy of mingled suppression of death returns and exaggeration of population figures."

The point of present interest, however, lies in the fact that the cities with highest death rates from all causes, as shown by the table, have lower death rates from typhoid fever and the diarrheal diseases than has this wonderful group of Lake cities. Thus, the mortality from typhoid fever per 10,000 population for the past five years has averaged for New Orleans—with a general death rate of 24.88 per thousand in 1894—only 2.14 per 10,000 from typhoid fever; Boston—general death rate 22.99—3.26 from typhoid; New York—general death rate, 21.03—2.04 from typhoid; Brooklyn—general death rate, 20.14—1.9 from typhoid; Philadelphia—general death rate, 18.28—4.8 from typhoid fever. Or, comparing the aggregates of the two groups of cities, it appears that while the five Lake cities had an average annual death rate from all causes of only 15.56 per thousand as against a similar average for the five cities last above enumerated of 20.62 per thousand, they had 4.76 deaths per 10,000 from typhoid fever, as against only 2.83 typhoid-fever deaths per 10,000 in the five contrasted cities. In other words, while the general death rate was 24.5 per cent. less in the Lake cities, it was 40 per cent. higher from typhoid fever.

These figures, which—whatever their individual inaccuracies—are sufficiently large to generalize from, lend pertinence to the recent comments of a sanitary engineer on the discharge of sewage into the waters of the Great Lakes and into tide water.<sup>1</sup> In perhaps no other respect, says this writer, has the progress of sanitary engineering run more directly counter to the original popular notions in regard to sewage disposal than in the matter of the discharge of sewage and garbage into either tide water or the waters of the Great Lakes. "In the early days of the discussion of the sewage question in general, it was thought that any system by which sewers could be emptied into either of those classes of waters was, if not perfection, at least so near it that the difference was practically nothing. Tide water, especially along the seashore, was generally considered to be the ideal receptacle for cities and towns, the large body of water affected being so great that the degree of dilution was deemed sufficient to render the effects of contamination practically nil; and essentially the same assumption was employed to justify the use of the waters of the Great Lakes for the same purpose by the cities located along their shores."

Practical experience has demonstrated what science had already predicated upon the known laws of

<sup>1</sup> The Engineering Record, June 8, 1895.

diffusion, sedimentation and purification of polluted waters. The disposal of sewage in a water supply is a sanitary atrocity which future generations will refuse to condone. Sooner or later, if communities will not protect themselves from such a revolting violation of sanitary common sense, the general government must intervene and positively prohibit the discharge of untreated sewage or other pollution into any stream or body of water whatsoever. The figures herein cited are of themselves a sufficient argument for such intervention at once, but they lack the force they would have if promulgated by some authoritative body.

*Let us have a Department of Public Health!*

#### SOME PATHOLOGIC RELATIONS OF LUSCHKA'S TONSIL.

Mouth-breathing, imperfect development of the chest, anoxemia, general mal-nutrition and impaired intelligence are generally acknowledged, since the researches of W. MEYER, a quarter of a century ago, to be among the direct consequences of hypertrophy of the adenoid structure in the upper portion of the naso-pharynx, just as truly as deafness and catarrh of the upper respiratory tract are also symptomatic of this condition. HARRISON ALLEN, in a short communication to the Pennsylvania State Medical Society (read May 22), has still further elucidated this subject by contributing the results of his recent pathologic and clinical observations. In addition to the classical form of obstructive disorder having its site in the pharyngeal tonsil, ALLEN recognizes two others, each of which have interesting clinical relations which are well worth attention and investigation. The three forms of adenoid disease of the pharynx, in accordance with this classification, therefore, will be:

1. Hypertrophy, with mechanical obstruction to respiration.

2. Deformity of the bony walls of the naso-pharynx, causing the normal adenoid mass to obstruct nasal respiration; and

3. A non-obstructing growth in a capacious naso-pharynx, which acts, in some unknown manner, so as to seriously disturb the general health of the patient.

The first class is sufficiently familiar to clinical observers, and need not be dilated upon. In the second class, the interest lies not so much with the adenoid structure as with the abnormal conformation of the skull, which causes a small adenoid mass to obstruct a narrow, acutely-angulated naso-pharynx. The subjects of this are often micro-cephalic and cretinoid, and are frequently met with in institutions for the feeble-minded, although occasionally such patients are also seen in private practice. The con-

dition is obvious upon inspection or digital exploration; the diagnosis is promptly made and the treatment is identical with the first class, avulsion of the greater part of the mass, and applications of astringents and detergents. E. FLETCHER INGALS, in an analysis of one hundred cases presenting hypertrophy of the pharyngeal or Luschka's tonsil,<sup>1</sup> expressed the opinion that in at least 90 per cent. of these cases the disease occurred in infancy or very early childhood, and he doubted very much whether the disease is ever developed after puberty. Some are probably congenital in origin and, in at least 10 per cent., it appears to be hereditary, several cases occurring in the same family. Improvement in intelligence and nutrition is very evident after operation, the patient often gaining 30 per cent. in weight within six months.

The third group deserves special consideration. It constitutes what ALLEN terms a veritable "adenoid disease." Here there are no symptoms of obstruction complained of, the vault of the pharynx is capacious and, after careful examination, no material increase of adenoid tissue can be discovered. The size of the mass, in truth, appears to be relatively unimportant; the fact that the mass itself is mischievous is of great importance in this class of patients. In view of the evident impairment of health in these cases,—and the gravity of the disorder is greatest in children on account of the lowering of vitality and defective development, amounting often to a veritable cachexia—ALLEN proposes the name of "adenoid disease" for this group. Indeed, such cases could scarcely, with propriety be called adenoid hypertrophy, because there is no hypertrophy, or, if it be present the moderate increase in size of the adenoid mass is relatively insignificant, existing as it usually does in a roomy naso-pharynx. In class second this peculiar condition may also exist, however, and, in a word, adenoid disease may or may not be associated with mechanical obstruction to breathing.

The novel and original suggestion of ALLEN, which makes this a decidedly valuable contribution to the pathology of new growths in the pharynx, is that there is a possible clinical relation existing between the pituitary body and the glandular mass lying immediately beneath it in the vault of the pharynx. In early life there is a canal through the base of the skull, which is a direct channel of communication between these two anatomic structures which, moreover, have many histologic features in common. It was suggested many years ago by OWEN that this canal and the pituitary body are a part of the remains of a primitive esophagus. The lower half of the pituitary body is largely composed of the same character of glandular and epithelial elements as

<sup>1</sup> The JOURNAL, Sept. 29, 1894.

constitute the mass of adenoid tissue to which reference has been made.

Recent investigations into akromegaly, giant growth, and various profound nutritive disorders, have shown them to be associated with increased growth of the pituitary body. Analogy would suggest that similar nutritive disturbances might follow adenoid disease of the naso-pharynx. In point of fact, ALLEN has reported several cases of this kind in which unexpected amelioration followed extirpation of the adenoid mass. The thought is suggested that even in typical cases of akromegaly, this simple operation might produce some change with possible improvement in the condition. For this application ALLEN is not to be held responsible, however, but the suggestion seems germane and especially noteworthy on account of the paucity of our therapeutic resources in this strange affection.

It is to be observed, on the other hand, that general treatment is often necessary. HOLBROOK CURTIS, of New York, last year reported a case of myxedema to the Section on Laryngology, in which it was noted that there was atrophy of the glandular tissues of the pharyngeal vault. Striking improvement in the mental condition and the general health of this patient followed the administration of a preparation of thyroid extract.<sup>2</sup>

In order to establish the pathologic and clinical relations of adenoid disease, it will be necessary, as opportunity offers, to make careful post-mortem observations of the brain and naso-pharynx. ALLEN suggests that in such examinations, the base of the skull embracing the membrane and outgrowth from the pharyngeal vault, the pituitary fossa and pituitary body, be removed as in a single piece, and this be prepared in the usual manner for microscopic examination. Together with this, the pineal gland should be preserved and examined. Such studies of the morbid anatomy of these cases may throw a flood of light upon the etiology of certain disorders apparently having their origin in this part of the body. Adenoid disease is allied to disease of other parts of the great lymph systems of the human organism and their special differentiations. It is necessary, therefore, to study it, as suggested by ALLEN, in the same careful manner as akromegaly, myxedema and allied affections have been investigated.

#### CONSERVATIVE GYNECOLOGY.

The late meeting of the American Gynecological Society had one very pleasant feature. Most gynecologic meetings of late years are so apt to be assemblages where exhibition of gory tumors and statistics of radical operations are made the subject of the leading discussions, that it does one good to re-

port that the article which created the most enthusiasm was one read by DR. FERNAND HENROTIN, of Chicago, on a conservative method of treating inflammatory pelvic affections in their incipiency by a minor surgical procedure. This consists in making an incision behind the cervix as soon as the diagnosis is established, and penetrating the inflammatory focus with the finger, an iodoform gauze drain being inserted and left in place. Even after an illness of only six or seven days, the Doctor asserted, a pus cavity is usually found, and in twenty-seven cases so treated, no bad symptoms followed, and the patients recovered, all of them apparently cured, before the establishment of any of the destructive processes that generally lead to chronic invalidism and require laparotomy. While HENROTIN does not claim originality for making use of vaginal incisions, he pertinently points out the simplicity of his technique and particularly insists upon this procedure for the treatment of these diseases in their very beginning, that women may be treated and cured by simple and rational surgery before mutilating measures are necessary. He also reflects upon the value of this digital exploration of the inflamed organs in settling mooted questions in these troubles, the same as has been done in regard to appendicitis, chronic pelvic ailments, and many other diseases.

Time and experience will teach us whether these sanguine views are correct and reliable, but it is a hopeful sign to see our best gynecologists receive such conservative papers with pleasure and encouragement.

Regarding the treatment of chronic diseases by radical measures, it is doubtful if any advance, further than perfecting details will ever be made in the gynecology of the future, but in reviewing the field we must acknowledge that little has been done toward curing the poor woman who has just reached her couch of suffering with her first attack. The hot poultice, or the douche, or the drug does not seem to have materially lessened the number of our unfortunate sufferers, so that in retracing their footsteps back to the methods of the elder SIMPSON, and bending their energies to the development of conservative and prophylactic work, gynecologists are putting themselves in line with co-workers in other specialties and showing commendable scientific courage.

The specialist who will show us how to cure the pelvic sufferer without mutilation will, indeed, have reared a noble monument.

#### A SO-CALLED "AMERICAN QUACK" IN DUBLIN.

The *Medical Press and Circular*, June 5, pays editorial attention to a MRS. POTTS, Mrs. DR. LONGSHORE POTTS, in fact, as a well-known "American quack." It appears that this lady has before now proffered her medical talents to the Irish sick, and on neither

<sup>2</sup> The JOURNAL, VOL. XXIII, page 486.

occasion has she reaped any great harvest. She belongs to the lecturing fraternity whose specialty is the reproductive organs. This lady also sells a "trumpet pessary" and bloweth her own horn in a fluent and rotund manner; she is a "brazen speaker," says the *Press*. "Lecturers there are who hail from America, and who seek to make their living by orating on public platforms about matters which modest people would avoid mentioning, are always confident and are certain to fetch a number of impressible women. Our object in noticing this particular quack is to say that the idea that she holds any medical qualifications recognizable in this country is entirely erroneous, and it is well that the public should be informed with some exactness as to the status of American colleges, lest other persons may gain credit in this country for qualifications which they do not possess. In the States there are no less than one hundred and fourteen medical colleges; some of them, such as Harvard, Yale, and the University of Pennsylvania, are of the highest repute, others mere disreputable diploma shops. Every one of these colleges can grant diplomas, but no person can practice on such qualification until he shall have also passed an examination held by the authorities of the State in which the diploma is granted by examiners appointed by the Executive. If he passes this State examination he can be registered, and may practice within the boundaries of that State, but he becomes an unqualified practitioner the moment he moves into another State, and must pass the examining authority which has jurisdiction in his new domicile.

As a sort of informal guarantee for the educational status of certain of these one hundred and fourteen colleges, an 'American Medical College Association' has been formed by the more reputable of them, and no college or university is admitted to membership of this Association unless both its courses of study and its examinations are up to standard. There are thirty colleges in this Association, of which the Female Medical College of Philadelphia, of which MRS. LONGSHORE POTTS says that she is an M.D., is *not* one. It is, in fact, a small proprietary diploma shop which few have ever heard of, and fewer still, even in America, take any notice of. From the report of the United States Commission on Education we find that the course which this college professes to require extends over three years, but only twenty-two weeks in each year, while the more reputable colleges require thirty-five or forty weeks. Its educational course would not pass muster in the very humblest qualifying body in the United Kingdom and, as for its examinations, 'the least said soonest mended.' What of that? It is not the first time that a quack succeeded in gathering in a few gulls and a certain number of fees. What is truly astonishing is that beside a number of ladies and ministers of reli-

gion, who do not count, PROFESSOR DOWDEN, DR. CHETWODE CRAWLEY, the LORD MAYORS of Dublin, Liverpool and Glasgow, and SIR HENRY IRVING are advertised as having appended their names to MRS. POTTS' manifesto. It is true that these gentlemen, who ought to have known better, testified to nothing more than the genuineness, of which they could have no personal knowledge, of certain testimonials of American gushers, and they expressed no opinion whatsoever as to the attainments of the lady or the propriety of her proceedings; but they must have known that their authority would be used as a guarantee for everything this quack said or did."

Bearing in mind that the above is written by a Londoner, it is about as correct as would be expected. The chief unfairness of the article was in the caption reading: "The Status of American Diplomates in this Country (England)," because it gives the impression that the cattle of the POTTS variety are of the class of diplomate type referred to. But let not that weary us—let us next send to the non-appreciative shores of Albion some of our surplusage of mind-healers, Christian scientists, bone-setters, cancer doctors, *et id omne genus*. Albion scarcely yet knows what America can do for her.

#### KENTUCKY STATE MEDICAL SOCIETY.

It is eminently fitting that the fortieth annual meeting of the Kentucky State Medical Society should have been held in the historic town of Harrodsburg—the oldest in the State. One of the largest meetings in its history was held there on the 12th, 13th and 14th of June, under the Presidency of DR. J. B. MARVIN, of Louisville. Within a few miles of there, in 1809, was born McDOWELL, the father of ovariectomy. Harrodsburg, itself, is the birthplace of three of the society's honored members: DRs. JOHN G. CECIL, AP. MORGAN VANCE, and L. S. McMURTRY.

DR. HENRY MILLER, now deceased, for many years an active and esteemed practitioner of Louisville, was born there, struggling in his early practice to make a success in his native town, afterward of national renown, and a President of the AMERICAN MEDICAL ASSOCIATION.

The society was welcomed on behalf of the citizens, by MR. BEN LEE HARDIN, in one of his characteristic speeches.

The reports of the officers showed the society to be in a most prosperous condition. Under the admirable rulings of the President, the papers were dispatched with much celerity, and the participants in the discussions held to their prescribed limit. A discussion upon diphtheria occupied the first of the first day's session. It was the sense of those participating in this discussion that the serum treatment of diphtheria was a valuable agent, and should not be withheld in the treatment of any case.

The second day, hernia was the special order for discussion, participated in by papers from Drs. Wm. L. Rodman, J. M. Foster, Geo. S. Davis, H. J. Cowan, W. C. Dugan, Ap. Morgan Vance and H. H. Grant.

The special order for the third day was obstetrics, with papers by Drs. A. D. Price, John G. Cecil, and David Barrow, to be discussed by Drs. J. M. Harwood, B. Logan Holmes, and H. Brown. Among the special subjects discussed was intestinal anastomosis, by Dr. Aug. Schachner and H. H. Grant. Dr. Grant exhibited a special clamp devised by him for lateral anastomosis and which had been used successfully in sixteen cases on the dog, and in one case on the human. Drs. Ray, Cowan and Dabney contributed articles upon the eye. Dr. Henry E. Tuley upon the newborn, and other valuable articles were read.

The State Board of Health met in regular session June 13, and during their session refused certificates to three men making application for license to practice in the State, holding diplomas from the Atlanta Medical College. These men had attended one unofficial spring course at another college, and upon promises from the Atlanta College the same year, attended a regular course there, and were duly graduated the next spring. The college had been notified twice to appear before the Board, but had failed to do so. The applicants had the sympathy of the Board, as they attended the school believing they could legally graduate in this time, but under the Kentucky laws the certificates had to be refused.

The society, by its president, appointed a committee of five members on public policy to coöperate with the State Board of Health in securing the passage of necessary laws looking to the public health. This is an important step, for all innovations by scientific bodies are looked upon with suspicion by the majority of laymen, and the indorsement of the State Board by this committee will increase its usefulness.

Another important act of the society was the resolution requesting the secretary to communicate with the American Medical Association, conveying the indorsement by the State Society of the efforts to obtain the appointment of a member of the Cabinet to look after the national health. It is believed that by the concerted indorsement of all State societies that such an appointment will be made.

During the session, the President of the American Public Health Association, Dr. William Bailey, on behalf of the Association, invited the State Society to be present at the meeting of the Association in Denver, October 1, 2 and 3.

Not the least entertaining of the whole session was the reception and banquet given the visiting physicians by the Mercer County Medical Society at the residence of Dr. A. D. Price, where they were the recipients of true Kentucky hospitality.

The morning of the last day, the nominating committee announced the selection of the following as officers for the ensuing year:

President, Dr. John Lewis, of Georgetown; Vice-President, Dr. H. H. Grant, of Louisville; Secretary, Dr. Steele Bailey, of Stanford.

Lebanon was chosen for the next place of meeting.

The JOURNAL will publish an abstract of the proceedings next week.

#### DOCTOR MEDICINÆ CIVITATIS.

It is with pleasure that we note in the Annual Announcement of Rush Medical College of Chicago, the first step taken in this country to establish the post-graduate degree of Doctor Medicinæ Civitatis.

The degree of Doctor in State Medicine is not intended to be conferred as an empty honor or perfunctory gradus, but as an evidence of merit in study and acquirements.

The following is the portion of the announcement that mentions the matter:

##### DEGREE IN STATE MEDICINE.

1. The candidate must be a Doctor in Medicine, of not less than one year's standing.
  2. The name of the candidate must have been on the matriculation book at least eight months before the examinations.<sup>1</sup>
  3. The candidate must have completed, subsequent to registration, six months' practical instruction in a laboratory approved by the faculty, and also have studied, practically, outdoor sanitary work for four months, under an approved Officer of Health.
- The examination (which will be rigid) to be passed by the candidate is prescribed as follows:

##### EXAMINATION FOR DIPLOMA IN STATE MEDICINE.

*State Medicine and Hygiene.*—Examination by paper. Time two hours. Causation and prevention of disease. Contagion in different Diseases; incubation period in each. Congenital Diseases and Malformations. Diseases of Animals in relation to the Health of Man. Diseases of the Vegetable Kingdom. Failure of Crops in relation to the Health of Man. Famine diseases. Injurious effects of unsuitable Food, bad Air, unwholesome Dwellings, unhealthy Trades. Causes of Origin and Spread of Epidemics. Effects of Climate on Health. Principles of Bacteriology. Character and Life History of the more important Pathogenic Microorganisms. Quarantine, Disinfection, etc.

*Chemistry.*—Examination by paper and in laboratory. Time one and one-half hours. Air, Water and Articles of Food and Drink, including their Chemie and Microscopic Examination and Analysis. Chemico-geologic considerations affecting Water Supply. The Processes of Respiration and Combustion. Disinfectants and allied materials used for Deodorizing and the Treatment of Sewage. The Detection of Common Poisons and recognition of Injurious Pigments.

*Physics and Meteorology.*—Examination viva voce. Theory, Use and Exposure of Meteorologic Instruments; Measurements of Air Pressure; Draughts.

*Engineering.*—Examination by paper. Time one and one-half hours. Water Supply; Appliances for the Purification and Distribution of Water. House Drainage; Drains and Sewers; Ventilation and Flushing; Connections, Traps and Tests, Apparatus connected with the construction, fitting and use of Water Closets; Disposal of Sewage. Ventilation and Heating.

*Morbid Anatomy.*—Examination viva voce. Examination based on the method of conducting Post-mortem Examinations and the recognition of characteristic Pathologic Specimens.

*Vital Statistics.*—Examination by paper. Time one and one-half hours. Statistics of Births and Deaths; Birth rates and Death rates; their relation to Age, Sex, Occupation and

<sup>1</sup> This condition does not apply to those registered in 1895.

Density of Population; their value as measures of the Health of Communities. Population; Causes of Increase and Decrease of Population; Estimates of Population, and their relation to Births, Deaths and Migration. Construction of Tables of Vital Statistics.

*Medical Jurisprudence.*—Examination viva voce. Personal identity; Age, Sex. Medico-legal relations of Pregnancy and Parturition. Signs of Death; Wounds and other injuries; detection of Blood. The Commoner Poisons (not including their detection by Chemic Analysis).

*Law.*—Examination by paper. Time one and one-half hours. Greenleaf on Evidence. Public Health Acts of the United States, and of the State where candidate lives. Practice of Medicine Acts in the State where the candidate lives.

Candidates are requested to send in their names to the Registrar at least a week before the first day of examination. The examinations will begin February 1.

Other colleges will doubtless follow the example thus set, and there is little question but in a short time there will be educated Health Officers to supply all demands. The time has come when State Medicine must be recognized as a special department of medicine.

## CORRESPONDENCE.

### A New Evacuator.

DEXTER, IOWA, June 9, 1895.

*To the Editor:*—Having had occasion a few months since to use Bigelow's evacuator in doing the operation of litholapaxy, I discovered the instrument was sadly defective in the manner of the connection between the rubber bulb and the glass bulb for receiving the *débris*; it being made by securing the rim of the glass bulb to a metallic ring by means of plaster-of-Paris; this metallic ring being in turn adjusted to the metal connection of the lower end of the rubber bulb by means of a bayonet joint on one side only. After evacuating about half of the crushed stone from the bladder, I found that there was a large leak from the plaster-of-Paris joint, as well as a smaller one from the bayonet joint above. The leak increased so rapidly that in a few moments more the instrument became practically useless and I was compelled to leave the operation in this unfinished state. In looking the matter up, I found that other operators had met with a similar experience, an experience about as trying as could well be imagined.

I concluded that it was desirable to have an evacuator with this connection made of other material than plaster-of-Paris, which is excellent as long as the instrument is kept out of the water, but rapidly becomes loosened when in actual use. I, therefore, devised the connection below described and illustrated, which on subsequent actual use, I found to remain perfectly water- and air-tight, regardless of the amount of pressure put upon it in manipulating the rubber bulb. The improvement consists: 1, in having two bayonet joints, instead of one, for making the connection with the ring on the rubber bulb; 2, and this is most essential—making a section of the metal ring for receiving the

glass bulb, and arranging for the closing of this section by means of a screw running parallel with the upper surface of the ring. Finally, in cutting on the lower inner surface of this ring, a deep groove to receive the flange of the glass bulb. Insert the glass bulb, remove the screw with a screw-driver, or similar instrument, spread the ring sufficiently to allow the flange to be received within the groove, adjust a soft rubber washer between the glass flange and the lower side of the groove, close the ring by means of the screw, and we have a perfectly tight joint that will not be affected by water. A second soft rubber washer is used between the metal ring of the rubber bulb, and the upper surface of the flange or glass bulb. The device was nicely made for me by Chas. Truax, Greene & Co., of Chicago.

M. G. SLOAN, M.D.

### More than Fifty Years.

FULTON, N. Y., May 8, 1895.

*To the Editor:*—Referring to the letter of Dr. Colvin, of Clyde, N. Y., in the JOURNAL of May 4, I have to say that I have practiced fifty-four years—fifty-two years of married life—fifty years' residence in the same house.

I became a member of the Oswego County Medical Society in 1842. Attended fifty of its annual meetings in succession; a member of the New York State Medical Society in 1858, and a member of the AMERICAN MEDICAL ASSOCIATION ever since its second meeting in Philadelphia.

CHAS. G. BACON, M.D.

## PUBLIC HEALTH.

**Bacteria of Graveyard Soil.**—Dr. E. H. Wilson, Bacteriologist of the Brooklyn City Board of Health, has submitted a report of his investigations on fragments of coffins sent him from some of the Brooklyn suburban cemeteries. He says, in substance, that while these fragments contain, as might be expected, a large variety of bacteria, no pathogenic varieties have been found; that the popular idea that all bacteria are dangerous is a totally erroneous one. The bacteria which are engaged in the process of destructive decomposition of the body are doing a beneficent work in returning to the soil the elements of which the body is composed, in a condition to be readily assimilated by the higher plants. Investigation has shown that the soil of graveyards contain no more bacteria in proportion than the soil of other places, especially below a certain depth. "In conclusion, I would say that while the presence of coffin fragments several years old is not to be commended from a bacteriologic point of view they are comparatively harmless, and only remind us more forcibly of the fact that it is the living and not the dead from whom we may expect harm in this matter."

**To the Rescue of the Oyster.**—After all the recent abuse of that "child of the rock and of the hoary sea," the oyster, as an infection-carrier and as a "scavenger of the sea" it will be consoling next September to recall the good words spoken for the bivalve at a recent séance of the Paris Academy of Medicine. M. Chatin stated that for some time he had pointed out the richness of oysters in bromin, iodine and fluorin. He wished now to make known the great quantity of phosphorus which oysters contain in an organic and, consequently, assimilable combination. The Portuguese oysters are the richest of all in phosphorus. Each of them contains very nearly one-twelfth of a grain of phosphorus; ordinary oysters have about one-third of this amount. These mollusks are equally rich in iron, their brown color being due to diatoms. A great number of infusoria on which the oysters feed are filled with these diatoms which are so rich in iron that the ash from burning them is of a deep red

color. M. Gautier remarked that all sea food is very rich in phosphorus in the organic state; thus cod-liver oil contains phospho-glyceric acid besides its alkaloid. M. Le Roy de Mericourt stated that he had a long time ago indicated the service rendered by oysters in the alimentation of persons attacked with chronic diarrhea in tropical countries.<sup>1</sup>

**Septic Vaccine.**—Dr. Gustav Fütterer, Professor of Physical Diagnosis in the Chicago Policlinic, communicates some rather alarming information concerning the vaccine points of commerce. With all necessary aseptic precautions on his own part, he finds on bacteriologic investigation at least one kind of microorganism present on every point examined. Some of these, it is true, are of little importance, but it will throw considerable light on the frequent untoward sequelæ of vaccination to learn that out of seventy-five points obtained from different sources and submitted to detailed examination fifty-five—or 73 per cent.—revealed the presence of pathogenic microorganisms, the streptococcus aureus, etc., and ten—or 13 per cent.—were infected with the streptococci of erysipelas and phlegmon. Dr. Fütterer announces<sup>2</sup> that he is at present, by experiment and practice, trying to answer the following questions: 1, which is the best way to disinfect these points and how may they be kept in an aseptic condition? 2, how should aseptic vaccine be kept and carried around for practical use? 3, how can septic vaccine be made aseptic and kept without impairing its properties as an effective vaccine medium? The last point must be well considered, since a vaccine that has been found to be aseptic once may not always be so and even if it is it can easily be contaminated by opening the bottle for use. It would certainly be safer if a disinfecting agent was added that would not only destroy the germs already contained in the vaccine fluid, but also those entering later.

**A Board of Health Circular on Tuberculosis.**—The Health Commissioner of Brooklyn, N. Y., Dr. Z. T. Emery, has drawn up the following circular for the guidance of the laity in respect of the questions of household sanitation that are constantly arising in every large city:

#### THE PREVENTION OF CONSUMPTION.

Consumption is a dangerous, infectious, communicable disease and can be prevented by simple and easy means of cleanliness on the part of those affected and those having the care of them. It is transmitted, in the vast majority of cases, from the sick to the healthy by means of the sputum or expectoration of those afflicted with the disease. *It should be remembered that the dangerous element is the expectoration of consumptives, and that if this is destroyed before it becomes dry, little danger is to be feared.* The expectoration should be received if the patient is confined to the house, into cups containing carbolic acid (1 part of the acid to 20 of water), or if the patient is up and about, on pieces of cloth which should be saved and burned at the first opportunity. This precaution is as necessary for the consumptive as for those about him, as many cases would get well if they would avoid re-infecting themselves. Consumptives should not spit on the sidewalks, or in public conveyances or in places of public congregation. Cases of consumption should be reported to the Health Department, not with a view of quarantining or otherwise interfering with them, but that the department may place in their hands simple instructions to prevent their communicating the disease to those around them and to assist in their own recovery. Apartments which have been occupied by consumptives should not be occupied by others until they have been renovated. They should be cleaned, scrubbed, whitewashed, painted or papered, as the case may be, before they are again occupied. Bedding, clothing, carpets, rugs, etc., used by consumptives should be disinfected, preferably by the Health Department.

**A Russian Test of Vaccination.**—The St. Petersburg correspondent of the London *Lancet* furnishes an abstract of a dissertation on smallpox and vaccination, presented to the

St. Petersburg Academy of Medicine last year, which is interesting as much from the results set forth as from the rarity of Russian statistics on these subjects. The author, Dr. A. N. Sotin, was led to collect his statistics in the following manner: the *volost*, or subdistrict, of which he was in charge, lay in the western corner of the Mologa *uyezd* or district, in the government of Yaroslavl. Observing that an epidemic of smallpox was approaching from the East, Dr. Sotin personally examined every child under 14 years of age in his district before the disease arrived. The total number of children examined was 1,564, distributed among 665 families and in 30 villages. He found that 1,055 had been vaccinated and had visible scars; 75 children formed a second group of doubtful cases, which were said to have been vaccinated, but on which no scars were visible; and 434 had never been vaccinated. The smallpox arrived and a widespread, though not very fatal, epidemic resulted. It was then found that of the 1,055 "vaccinated" children only 16, or 1.3 per cent. had contracted the disease; of the 75 "doubtful" 35, or 46.6 per cent. suffered; while of the 434 "unvaccinated" children as many as 244, or 58.6 per cent., caught the disease. In other words, the unvaccinated suffered to an extent forty-five times as great as the vaccinated. Further, it was observed that in 189 families all the children were unvaccinated, and in these families if one child sickened with the smallpox the disease spread, with only seventeen exceptions, to every other child in the house. On the other hand, in houses where some children were vaccinated and others not, the disease always attacked the last and the first escaped. Dr. Sotin believes that there is no danger from vaccination performed during a smallpox epidemic, but that general vaccination will with certainty cut short an epidemic, and that the immunity following vaccination does not last more than eight years, at the end of which time re-vaccination is necessary.

**Health Reports.**—The following health reports have been received by the Supervising Surgeon-General M.-H. S.:

#### SMALLPOX—FOREIGN.

Argentina Republic: Buenos Ayres, March 1 to 31, 12 deaths.  
Austria: Buda-Pesth, May 17 to 27, 7 cases, 1 death.  
Belgium: Antwerp, May 13 to 18, 3 deaths; Brussels, May 18 to 25, 1 death.  
Bohemia: Prague, May 18 to 25, 3 cases.  
Brazil: Rio de Janeiro, May 4 to 18, 6 deaths.  
Cuba: Havana, May 31 to June 6, 5 deaths.  
Egypt: Cairo, May 6 to 13, 5 deaths.  
England: Liverpool, May 25 to June 1, 2 cases.  
Greece: Athens, January 15 to May 28, 147 cases, 23 deaths; Piræus, January 15 to May 28, 189 cases, 46 deaths.  
India: Calcutta, April 27 to May 4, 98 deaths.  
Ireland: Dublin, May 25 to June 1, 10 cases, 1 death.  
Mexico: Nogales, June 1 to 8, 1 case.  
Russia: Batoum, May 21 to 28, 17 cases, 1 death; Odessa, May 18 to 25, 6 cases, 1 death; Warsaw, April 18 to 25, 1 death.  
Turkey: Constantinople, April 1 to 30, 62 deaths.  
Uruguay: Montevideo, May 4 to 11, 1 case.

#### SMALLPOX—UNITED STATES.

Colorado: Pueblo, June 1 to 8, 1 case.  
Illinois: Chicago, January 1 to April 30, 126 deaths.  
Indiana: Evansville, June 14, 2 cases.  
Louisiana: New Orleans, May 11 to 18, 8 deaths.  
Michigan: Detroit, Battle Creek, Olivet, smallpox reported present June 1 to 8.  
Missouri: St. Louis, May 1 to 31, 26 cases, 7 deaths; June 1 to 8, 3 cases, 1 death.  
Pennsylvania: Philadelphia, June 1 to 8, 8 cases.  
Ohio: Cincinnati, June 7 to 14, 4 cases.  
Virginia: Lexington, June 14, 9 cases (none since May 26); Buena Vista, June 14, 8 cases (none since April 29); Lowmoor, June 14, smallpox cases reported: Staunton, April 28 to June 12, 105 cases, 5 deaths.  
Wisconsin: Milwaukee, May 1 to 31, 19 cases, 1 death.  
West Virginia: Wheeling, March 18 to June 15, 29 cases, 3 deaths.

#### CHOLERA.

Brazil: Rio de Janeiro, May 11 to 18, 1 death.  
India: Calcutta, April 27 to May 4, 71 deaths.  
Turkey: Constantinople, April 1 to 30, 24 deaths.

<sup>1</sup> Le Bulletin Medical, May 22, 1895.

<sup>2</sup> Chicago Medical Recorder, June, 1895.

## YELLOW FEVER.

Brazil: Rio de Janeiro, May 4 to 18, 62 deaths; Santos, April 26 to May 3, 105 cases, 96 deaths.

Cuba: Havana, May 31 to June 6, 5 cases; Santiago de Cuba, June 1 to 8, 16 cases, 8 deaths.

Mexico: Mazatlan, May 20, yellow fever reported to be present; Vera Cruz, May 31 to June 6, 5 deaths.

## CONSULATE OF THE UNITED STATES.

ATHENS, May 28, 1895.

I have the honor to report that since the appearance of smallpox in Athens and the Piræus, about the middle of January, there have been in all 336 cases; 189 in the Piræus, 147 in Athens. Of these, 249 had been recently vaccinated, and 37 in childhood. Sixty-nine deaths occurred, 23 in Athens and 46 in the Piræus. A large percentage of the deaths was of young children, or people of evil habits of life.

There are now 26 patients in the hospital at Piræus; 69 in that of Gondé near Athens. Only one or two cases have been heard of in the last two or three days. Much credit is due to the authorities for their thorough and scientific handling of the epidemic. I am, sir, your obedient servant,  
GEORGE HORTON, United States Consul.

## CONSULATE OF THE UNITED STATES.

NOGALES, SONORA, MEXICO, May 20, 1895.

I have the honor to inform you that reports are current in this vicinity, as well as in other portions of this State of Sonora, that at Mazatlan, a seaport city on the western side of Mexico (in the State of Sinaloa), yellow fever is now prevailing to a considerable extent, and that in some instances the disease has terminated fatally. It is also reported that there have recently been two cases of the disease at the city of Guaymas, another Mexican seaport (by rail, some two hundred and sixty miles south of Nogales). I have been unable to verify the reports in either instance, but I am apprehensive that they are not without some foundation. I am, Sir, your obedient servant,  
FRANK W. ROBERTS,  
United States Consul.

RIO DE JANEIRO, May 21, 1895.

I have the honor to inclose report for the week ending May 18, 1895. There were 12 deaths from *accessio pernicioso*, an increase of 3; 30 from yellow fever, a decrease of 2; 4 from beriberi, a decrease of 3; 3 from enteric fever, a decrease of 1; 1 from measles, the same as in the foregoing week; 1 from cholera and 1 from cholera, none in the previous week; 7 from choleraform diarrhea, an increase of 6; 1 from choleraform enteritis, and 1 from whooping cough, none in the previous week; 53 from consumption, an increase of 20. There were 358 deaths from all causes during the week, which is an increase of 32.

While there is really no disease reigning considered here as epidemic, yet great caution is needed where there are so many different kinds of contagious affections, though in very small numbers for the population.

Cholera. I am a little surprised that a case of cholera, or as they call it here, cholera morbus, should be reported, as the disease appears to be finished in the places of its first appearance, and it is almost unheard of here now, but as you will see, by the report choleraic diseases still occur. The sanitary measures adopted for the ways of communication with the interior have been suspended as no longer necessary, but vigilance is still kept up.

Yellow fever. There is more of this disease here now than during the summer months, but the cases are scattered and it is now declining.

Plate River. Cholera has been officially declared extinct in Buenos Ayres, though cases appear in Montevideo. The authorities in those towns have declared the Brazilian ports—except Santos—free from suspected disease, but they still disinfect ships arriving from Brazil.

Respectfully yours,

R. CLEARY, M.D.  
Sanitary Inspector M.-H. S.

## CONSULATE OF THE UNITED STATES.

FOOCHOW, CHINA, April 30, 1895.

I have the honor to inform you that the disease known as the "Hong Kong Plague" has made its appearance in Foochow, and is already established as an epidemic. It is confined to the city of Foochow proper, most of the deaths from the disease occurring within the city walls near the eastern and western gates, respectively; but it is stated that several cases have occurred among the natives of a village situated on the Island of Nantai in the vicinity of the foreign settlement, though I am unable to say that the Nantai cases are real cases of the plague.

There is no question or doubt about the epidemic in the city being identical with that which last year caused such mortality in Hong Kong, and in Canton and other southern Chinese ports. The symptoms attending its appearance and progress unmistakably stamp it as the plague; and in the infected districts within the city the rats are dying in great numbers, just as has been the invariable rule wherever the plague has shown itself in the past.

The health of the port, in general, as respects natives and foreigners has been exceptionally bad this year. Some sporadic cases of cholera have already occurred; and it is possible that there will be suffering from an epidemic of cholera along with that caused by the plague.

In a city like Foochow it is impossible to institute any sort of sanitary measures to prevent the spread of contagious diseases, or to even mitigate the suffering of the victims. So, unless the present epidemic die out of its own accord, there is every prospect that misery and death will come to thousands of the one and a half millions of people living in the city proper and its immediate suburbs.

At an early date I shall report more fully upon the situation.

I have the honor to be, Sir,

Your obedient servant,

J. COURTNEY HIXSON, Consul.

## NECROLOGY.

FRANK LYMAN FORSYTH, M.D., of Providence, R. I., May 11, 1895. He was the son of Dr. Francis Flint Forsyth, an eminent physician in Massachusetts, who was for many years one of the counsellors of the Massachusetts Medical Society. Both father and son were members of this society, the son being also a member of the Rhode Island Medical Society and the AMERICAN MEDICAL ASSOCIATION. He was born at Hampton, N. H., Feb. 13, 1854, and received his degree from the Harvard Medical College in 1877, after preparatory study at the Boston Latin School and the High School at Weymouth, Mass. An appointment was soon obtained at the Rhode Island Hospital where he remained one year. He supplemented his education at Harvard by a post-graduate course in 1891. His practice was large and successful and extended over a period of seventeen years, but his health began to fail nearly a year ago, and although the winter was spent in the South he passed away in eighteen days after his return. He was interested in several fraternities, was a member of the I. O. O. F., a past chief patriarch of Narragansett Encampment, and in 1887-88 was grand chancellor of the Grand Lodge of K. of P. of Rhode Island. He was a Mason in Nestell Lodge, No. 37, A. F. and A. M., and a member of Providence R. A. Chapter, Providence Council, R. and S. M., and St. John's Commandery, No. 1, K. T. From 1886 until 1890 he was grand secretary of the Grand Clan of Rhode Island, O. S. C., and in 1890 he was elected grand chieftain of that body. His widow survives him.

CALVIN TRUESDALE, M.D., of Rock Island, Ill., died June 9. Dr. Truesdale was born in Northern Ohio in October, 1822, and was consequently 73 years old. He graduated from the Western Reserve Medical College in 1845. After practicing some years in Ohio, he came to Rock Island in 1854, and continued in the practice of medicine there from that time till his last illness, a period of forty-one years, years which brought to him success in his profession and a competency, beside the respect of the community and public and professional honors. He was surgeon of the Rock Island division of the C., B. & Q. Railway, and one of the stockholders of the Rock Island Plow Company, beside being actively interested in the general welfare of the city of Rock Island. During his residence there he was twice elected mayor of Rock Island, and in 1872 was a candidate for Congress. He was spoken of a number of times later for like candidacy, being a man of acknowledged intellect and influence, and one whose loss will be mourned by many. He was married in Ohio in 1851, and

## ADDRESS.

### ADDRESS ON THE FOUNDING OF THE ILLINOIS HOSPITAL.

Delivered in Central Music Hall, June 12, 1895.

BY SETH SCOTT BISHOP, M.D.

CHICAGO.

The purpose of this pleasant meeting, held under the auspices of the gallant Columbian Knights, is not a mercenary but a merciful one. There are some good people who entertain the idea that doctors are like ministers—in one respect—that they are always asking and receiving. These are the excellent citizens who pay their bills. There is another large class who realize that doctors are persistent askers but poor getters. These are the beneficiaries of our good-natured Esculapians, but they would have their doctors work for nothing, board themselves and go to the Chicago River to drink. Medical men have learned, perforce, that it is more blessed to give than to receive, and we are not here to ask more than we are willing to give.

Every prosperous citizen owes a certain obligation to the community to which he is indebted for his prosperity. There may be poetry but there is no romance or fiction in my remark that doctors work for nothing. I speak from experience. During the past fifteen years I have served on the staffs of more than half a dozen of our charity hospitals and dispensaries, and, like all the other attending physicians, have never been paid a dollar by any one of them. But once in a while the sweet, strange melody of "thank you" tickles the auditory nerve. I am often asked: "Why do you work without pay?" I will tell you our secrets. First of all, we love our work. No other citizen endures more trying ordeals, or subjects himself to greater personal sacrifices for the pure love of his labor than the conscientious charity physician. By this means, also, he becomes perfected in his art and known for his skill. There is a satisfaction, a fascination about the medical and surgical treatment of large numbers of our fellow beings that words can not portray. Who would not be a valiant knight, the general of an army, or even a colonel—if he could? Who would not risk his ease and comfort to save a man or helpless horse from death?

Do we need another hospital? If you have tried to secure the admission of poor patients to our hospitals since the World's Fair you will answer this question in the affirmative. It is difficult for influential physicians to open the hospital doors to their own patients, and next to impossible for you to find an empty cot for your sick or injured friend. The city has outgrown its hospital facilities. The county institution is over-full. There ought to be a district hospital in every populous ward. Much suffering and many lives could thus be saved. The chances

of the sick, and of the wounded who are subject to shock and bleeding, are imperiled by long jaunts in ambulances over jolting pavements to far-distant hospitals.

The 16th and 17th wards have no hospitals. In the 17th ward alone we have 30,000 people, enough to constitute a city of importance. Over one-half are foreign-born, mostly Scandinavians, and more than one-third are under 21 years—our rising generation. And here, young ladies, is a pointer for you: there are 3,200 more males than females. An army of stalwart young men is encamped in the boarding houses in the eastern half of this ward.

The 17th ward is about a mile and a quarter square, bounded on the north and east by the river, on the south by Lake Street and on the west by May and Carpenter Streets. It contains eighty-five factories, half a dozen railroads, an elevated road and numerous street car lines with their many accidents. Our young Illinois Hospital is situated in the heart of this district on the six corners of Milwaukee and Austin Avenues and North Union Street. A cable car line passes the door and three other car lines are within a square. There is no other hospital nearer the center of this busy little world than two miles distant. The people are poor and need our help. The strong should lend a hand to the weak. It is good political economy to give aid to the ailing in time to restore their health, save their injured limbs and restore them to their vocations in the capacity of producers, rather than to allow them, through neglect, to become perpetual paupers, beggars or criminals. To a business man this is a proposition that appeals to good sense if not to sentiment. It is a paying investment for citizens to combine their efforts with the doctors' work in such humanitarian institutions. Physicians contribute their time, their talent and their strength, and as much money as they can afford. Is it just to ask them to go farther and bear the entire burden of these charities for the community whose duty it is to provide housing, board and nursing for their sick poor?

We have made a discovery in the 17th ward. We happened upon a determined little band of noble souls who had imposed upon themselves the duty of living in the midst of this colony for educational purposes. They are there as brothers and sisters to help those who need help, to teach those who want to learn, to promote cleanliness, purity and peace—in a word, to make intelligent, patriotic American citizens. Without sect or sectionalism they cultivate the spirit of universal brotherhood and practical Christianity. The founding of a dispensary and hospital in this neglected spot is due to the open arms that welcomed us to this self-sacrificing settlement—the Chicago Commons. Long life and success to the Chicago Commons! They need and merit your help. They are our willing allies. Our interests are mutual.

We appeal to the people to rally to our aid. The love of humanity should call forth the generosity of our fortunate few. The memory of Newberry, Cre-rar, Jones and Lewis shall live when their tombstones are no more. The high examples of Rockefeller and Field should not be lost on those who wish to witness the blessings of their benefactions while they live. Who will be our Scoville of great heart, and our Dr. Pearsons of many noble deeds? Or who will be our Mrs. Pearsons with her \$10,000 gift to Anatolia College, presided over by my classmate?

Great souls are these—products of this century and this civilization—superior to any other! Their memory shall bloom when monuments crumble to dust. Their spirits shall animate the coming generations when their fellow-mortals sleep forgotten. What other benefactor of our race shall rise to bless his fellow-men? Who will sow the seeds of a lasting charity by endowing this refuge—this restorer of the helpless to health and happiness? And what more fitting place to appeal for brotherly love and sympathetic deeds than this platform, hallowed by that poetic preacher who dwelt like sunshine in our midst, consecrated to the cause of humanity and a broad Christianity, whose features, cast in classic mold, smile sweet benedictions on our cause—that moral philosopher and Christian philanthropist, David Swing!

## ORIGINAL ARTICLES.

### HISTORY OF THE CASE OF THE HON. WALTER Q. GRESHAM, LATE SEC- RETARY OF STATE OF THE UNITED STATES.

BY W. W. JOHNSTON, M.D.  
WASHINGTON, D.C.

Secretary Gresham was taken ill on April 30, the earliest symptoms appearing while he was at a Cabinet meeting; on the following day he was suffering from acute epigastric pain, which was so severe as to require the use of morphia hypodermatically. On May 3 the pain changed its location to the right infra-axillary region. By reference to the thermometric chart it will be seen that during these days he had fever. At this time he was under the care of another physician.

Early on the morning of May 4, I received a note asking me to call and see Secretary Gresham at the Arlington. I was requested by him to take charge of his case. The chief symptoms which were presented to me, at my first visit, were fever, embarrassed breathing, his voice being broken during conversation, and his facial expression indicating suffering; the pulse was 100 and not very strong and his respirations were 36 to the minute. He had slept several hours during the night, but sleep had been much disturbed by the dyspnea and by acute pain in the right side.

Physical examination of the chest showed the presence of a considerable amount of fluid in the right pleural cavity, dullness on percussion and aegophony reaching as high as the lower edge of the scapula. There was diminished expansion and entire absence of vocal fremitus over the same region.

The diagnosis was made of acute pleurisy with effusion on the right side; this opinion was based

upon the symptoms and physical signs described; there was no symptom, noted by me at the time, which could not be explained by this lesion, and there was no symptom which indicated any lesion of any of the abdominal viscera. Neither then nor at any subsequent period was there any icterus or abdominal tenderness, or unusual tympanitic distension.

A cantharidal plaster, six inches square, was applied over the right infra-scapular region, a liquid diet of koumiss and milk ordered and absolute rest enjoined. A mixture was prescribed containing the liquor ammoniae acetatis and tincture of digitalis. He was already under the care of a trained nurse, another one was secured to assist, and everything was done for his general comfort under the watchful supervision of Mrs. Gresham.

During the day the patient slept at intervals, and there was a good deal of discomfort in breathing; he was unable to lie on either side, but his symptoms did not change for the worse. The blister had vesicated well; this was dressed and the right side covered with cotton and oiled silk.

May 5. After 1 A.M. the night was comfortable; his temperature continued to drop until it reached 99.2 degrees at 6 A.M. At 9 A.M. an attempt to turn over, brought on a violent paroxysm of pain in the right side of the chest; for a time he breathed with difficulty, but as soon as the pain passed off, he was in no sense any worse than before. A water enema was followed by a large normal movement. At the morning visit the line of dullness on percussion showed the fluid was greater in amount, the respiration had increased to 40 and the pulse to 118 per minute, these being the maxima reached during this period of the illness; during the latter part of the day he was more comfortable, and slept three hours at intervals. Milk, koumiss and chicken broth were taken alternately and the ammonia and digitalis mixture was given, but not regularly.

May 6. During the night the patient slept in short naps; at 7 A.M. there was profuse perspiration; the temperature then being 98.2 degrees and he was nervous and restless. Later in the morning he felt better than before; a water enema gave him a small normal action and in the afternoon he slept three hours. The pleural effusion reached its maximum to-day, the dullness extending nearly to the spine of the scapula, but the breathing was not over 30 to the minute, the pulse 98; the greater ease in breathing seemed to be due to the relief from the constant and aggravated paroxysmal pains in the pleura which had been present up to this day, and which after this did not recur.

May 7. The patient slept moderately well during the night; in the early morning he was restless.

Mr. Gresham frequently, and generally in the morning, complained that he was suffering from indigestion, but there never was any objective evidence of this; his tongue was slightly coated and dry, and there were occasional eructations of gas, but as a rule digestion of the fluid food given was as well performed as it usually is in acute illness. During the day he had several short naps and seemed very comfortable, although he was at times anxious and nervous.

May 8. The patient slept between six and seven hours during the night, at times lying on his left side and breathing with no difficulty. He awoke

## RECORD OF TEMPERATURE, PULSE AND RESPIRATION, CASE OF SECRETARY GRESHAM.

much brighter than on any previous morning; his temperature was 98 degrees lower than at any previous time, his respirations were 26 and pulse 96. Three ounces of Hunyadi Janos water were given; as this had no effect, a water enema was administered later in the day and a small normal movement followed. The afternoon was comfortable but without sleep. The same diet was continued, but as he objected to the mixture and as he was doing so well this was discontinued.

There was no perceptible diminution of the fluid in the pleura, but no increase, and the general improvement and feeling of ease in breathing gave every encouragement of rapid absorption. The question of paracentesis was not considered, as no symptom called for operative interference.

May 9. The night was less comfortable than usual; he did not sleep well until between 2 and 7 in the morning. As he complained of indigestion, a powder of bismuth and bicarbonate of soda was given and later a water enema caused a small action. During the afternoon he slept at intervals; the nourishment of buttermilk or broth was taken regularly during the day.

May 10. The patient slept moderately well, but was disturbed by having two loose actions in the early morning. The morning and afternoon were passed comfortably; his food was relished more than at any previous times. As he complained of occasional and slight pain at the edge of the ribs on the right side, a small blister was applied to the right inframammary region and left until it caused vesication. To-day there was a perceptible beginning to the absorption of the effusion. All the symptoms were favorable, and beyond an occasional complaint of indigestion he spoke of nothing being wrong.

May 11. The daily decline in the temperature and the improvement in other symptoms had been uninterrupted up to this date. At 7 A.M. the temperature was higher than at any previous day at the same hour since May 5; it continued to rise during the day, reaching 101.6 degrees at 6 P.M.; from this hour it continued to drop until it reached 99 degrees at 7 A.M. on the next day. There was no apparent reason for this accidental interruption to the daily decline of the fever curve.

Dr. D. W. Prentiss met me in consultation and agreed with me as to the diagnosis and as to the favorable progress of the case; the pulse, respiration and temperature indicating a decline in the inflammation, and giving promise of early absorption of the fluid. A capsule of squills, digitalis and calomel was directed to be taken every four hours, and buttermilk, milk and Mellin's food or bouillon were given every two hours.

May 12. The night was very comfortable; there were several hours of sleep in the morning; as he wanted more food, tea and toast were given and, later, oyster broth. The temperature had fallen and he seemed to have recovered from the sudden rise of yesterday. Beyond an occasional sharp touch of pain on deep respiration there was no complaint to-day; the bowels were freely moved, and he was composed and cheerful. Although asking for the privilege of attending to business, he readily consented to give up everything that might delay his recovery.

May 13. From this date until May 25, there was a steady progress toward recovery from day to day. The fluid in the pleura rapidly diminished, the tem-

perature was normal and the pulse and respiration reached 76 and 18 respectively. The tongue became almost entirely clean, and there was a demand for solid food to satisfy the increase in appetite. The diet consisted of milk, buttermilk, ragout, toast and breakfast hominy. On May 16, a small bird was taken with relish, and from this day on he was allowed solid food once daily, and semi-solids and liquids at other hours. Now and then he complained of indigestion, but his appetite and desire for food was not at any time lost; the condition of the tongue, the character of the fecal discharges and the usually quiet sleep at night gave every evidence that digestion was being well performed. As his improvement was so marked Dr. Prentiss discontinued his consultation visits on May 18. No medicine was given during this time except a capsule containing quinia and nux vomica three times daily. Two or three times the elixir of chloralamid was tried when he complained of sleeplessness at night.

May 24. The night was passed most comfortably; he enjoyed his breakfast of a tender piece of steak with toast, and his dinner of a bird and toast, milk and bread and buttermilk being given at other hours. The nurse's record states that "the day was most comfortable," and he slept during the afternoon. A solution of dilute hydrochloric acid with pepsin was given after food.

No privileges were allowed the patient beyond the permission to look at an illustrated periodical for a few moments at a time; occasionally he sat in a semi-erect position supported with pillows; the same precautions were continued in every other respect as during the earlier part of his illness. Except for one visit from his private secretary he saw no one except members of his immediate family, and he did not attempt to attend to any matters of business. His manner was that of quiet content and satisfaction with his improvement.

May 25. The patient slept well; the record says he had a very good night. The examination of the chest showed the presence of a very small amount of fluid in the lower part of the pleural cavity; aegophony had almost entirely disappeared, the line of dullness was much lowered and there was a distinct return of expansion and normal vocal fremitus.

The gain had been so marked in the past few days that the expectation was held out to Mr. Gresham that he might be able to sit up by the side of his bed for a few minutes within three or four days. On the evening of this day, however, a sudden change in his condition destroyed all these well-founded hopes, and the overwhelming illness began which ended fatally on May 28. The first indication of this change appeared at 7:30 P.M.; he seemed uncomfortable and restless, and complained of epigastric uneasiness which very soon became a decided pain. About 11 P.M. he vomited a little greenish fluid and a few coagula of milk which he had taken about three hours before; there was no other undigested food in the matters vomited. The temperature began to rise at the same time and the pulse and respirations increased in frequency.

May 26. At 1 A.M. the pain was of so intense a character that it was found necessary to give him one-eighth of a grain of morphia hypodermatically. Mustard was applied to the epigastrium and liquid food was given in small quantities only. The night was restless, sleep being interrupted, but toward

morning there was some improvement in the symptoms. He again vomited in the afternoon. The pulse was frequent, not very strong and occasionally irregular. Milk with whisky and beef juice were given. One other dose of morphia was administered at 6:40 P.M. to relieve a very intense attack of pain, but after this it was not again required.

During the night the pain passed to the left side of the chest wall, and it was thought the attack would prove to be one of pleurisy on that side; a small blister was applied over the left infra-mammary region. The increase in the respirations and pulse and the continuance of fever gave grounds for believing that there was some new inflammatory process beginning in the chest. The pain and vomiting were thought to be reflex symptoms due to this cause and the subsequent progress of the case and its termination confirmed this opinion.

May 27. During the night the pulse had much less force, and food and stimulation were continued. There was no vomiting until 10:30 A.M. when a considerable amount of greenish fluid was thrown off.

Dr. Prentiss met me in consultation and on examining the chest we discovered solidification in the recently expanded lung on the right side. There was a decided area of dullness, where the percussion had been almost normal two days before, and there was some bronchial breathing with bronchophony over the same area. The conclusion reached was that there had been an extension of the inflammatory process to the pulmonary tissue and that the symptoms present were due to pneumonia suddenly developed in the right lung.

The care which had been taken and the avoidance of any imprudence or exposure precluded the idea that this attack was the result of "catching cold;" the nature and course of the illness showed that it was not primarily connected with digestion and, therefore, not due to the indigestion of the food taken.

The alarming symptom was the weakness of the heart's action. During the morning the pulse ranged from 128 to 135; nitro-glycerin and digitalis were administered but with little effect in giving strength to the heart. Up to 6 o'clock in the afternoon there was no alarm felt as to any immediate danger; at this time the pulse became more frequent and feeble and the dyspnea was more marked. Strychnia and nitro-glycerin were given hypodermatically at regular intervals and stimulating enemata employed. At 9 P.M. there was such a marked collapse that death seemed imminent; transfusion with a sterilized saline solution was made into the median-cephalic vein of the right arm; three pints were introduced with the effect of bringing back warmth to the extremities and some color to the face, the pulse also became fuller and stronger; but this effect was temporary only and by 11 o'clock the same symptoms of collapse returned. From this time the change was rapid. Consciousness was not altered until within a short time of the last moment. Death occurred at 1:15 A.M., May 28.

**Bellevue Hospital, New York.**—The Commissioners of Charities and Correction of New York City have determined to introduce the novelty of Turkish and Russian baths into that institution. Bids thereon are to be opened June 27, and the work will be pushed.

## NOTES OF A CASE OF ACUTE SUPPURATIVE PANCREATITIS WITH REPORT OF NECROPSY.

Read in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY I. E. ATKINSON, M.D.

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AND OF CLINICAL MEDICINE IN THE UNIVERSITY OF MARYLAND, BALTIMORE, MD.

Acute suppurative inflammation of the pancreas is so rarely recognized during the lifetime of the patient, that I have thought that the details of the following case, in which it was possible to make a correct diagnosis while the patient was yet alive, would prove sufficiently interesting to engage your attention for a few moments.

I was called to see, on Dec. 2, 1894, Mrs. S., the mother of two children, one 12 years, the other six months old. She was 35 years of age, with dark hair and eyes, tall and unusually stout, though it was thought she had lost nearly forty pounds during her illness. She had enjoyed excellent health until fifteen months previously when she was seized with a severe attack of what her physician told her was hepatic colic, and which was followed by intense jaundice within two days. The attack lasted three weeks, with the usual symptoms. No gall stone was recovered from the feces, though looked for. The pain was almost constant, though of unequal severity. After a very severe paroxysm it disappeared abruptly and the patient soon regained her health. She became pregnant almost immediately after, nearly eleven years after her first and only other pregnancy. She was safely delivered last June, did not nurse her baby and made a good convalescence. In August she was thrown over the dashboard of a dog-cart but was apparently unhurt. During the summer, for a month or more, was affected with slight diarrhea. Upon the last day of September she was suddenly seized with an attack which she recognized as identical in character with her former attack of hepatic colic. After two days, her urine became dark, her stools colorless, and jaundice supervened. Her pain was almost incessant though she did not take to her bed. After a while the intervals between the paroxysms of pain became longer, but no positive relief in its intensity was obtained, though the jaundice diminished and her feces became colored again. She continued to lose weight, her appetite and strength failed and she finally took to her bed, about four weeks previous to my first visit. The various remedies employed under medical advice gave only temporary and partial relief. Since taking to bed, she had had no sharp paroxysms of colicky pains, but had had frequently recurring milder pain, with persistent, though slight jaundice, and frequent vomiting, the ejected matter occasionally being streaked with blood.

At the date of my first visit, sixty-two days after the beginning of the attack, she was in bed, slightly jaundiced; her body was still well nourished. Her tongue was coated with a thin yellowish fur. She had no sore throat. The heart and lungs gave no abnormal sign. There was no expectoration and no cough. She was vomiting several times daily, almost without nausea, a greenish fluid, sometimes slightly bloody. The vomiting appeared to have no relation to the ingesta. The bowels were moved several times daily. The actions were semi-solid, grayish, and

contained lumps of mucus. This mild diarrhea and vomiting were said to have been present for several weeks. Hiccough had latterly been very troublesome. There was no splenic enlargement. Liver dullness began in the mammary line at the first rib, but did not extend beyond the costal arch. The body was somewhat distended with gas. In the epigastric region, extending into the left hypochondrium and reaching to within an inch and a half of the navel, was an induration, not modifying the outline of the abdominal wall, irregular in contour, not fluctuating, not movable, and but slightly tender to pressure; its diameter in the median line was about three inches and four and a half inches laterally, reaching to left mammary line. The percussion note over this tumor was relatively dull, not tympanitic. The lower abdomen showed no abnormality. The urine was abundant, darkened by bile pigment and faintly albuminous and with Fehling's solution gave a slight but positive sugar reaction. It was acid and of sp. gr. 1020. Though almost no pain was elicited by palpation, the patient complained of severe lancinating paroxysmal pain radiating from the epigastric region, with its point of greatest intensity under the xyphoid cartilage. She also suffered similar pain in the back, between the shoulders. The abdominal muscles remained almost motionless during respiration, which was almost purely costal and rapid, significantly so when considered with reference to the pulse rate and in the absence of signs of pulmonary disorder. Fever was said to have been present for many weeks, though recorded observations were not made until November 27. During the entire period of illness there had been no chill. Several weeks previously there had been a sensation of chilliness, but this had never recurred. Neither had there been sweating, except to a small extent about the head. She had at no time had symptoms of intestinal obstruction; on the contrary, there had been a notable tendency toward diarrhea almost constantly from the first. She was unable to lie upon either side and was most comfortable in a semi-recumbent, dorsal position. Exhaustion was great and sleep very insufficient and disturbed. An hour after my examination she vomited some fresh blood.

A consideration of all the symptoms and history seemed to justify the following diagnosis: hepatic colic at the outset of symptoms on September 30; impaction of the calculus at the common orifices of biliary and pancreatic ducts in the duodenum with incomplete obstruction. Inflammatory hyperemia with gradual formation of suppurative pancreatitis and peri-pancreatitis. The case progressed with varying but increasingly graver symptoms. The tumor gradually extended downward to the level of the navel. Diarrhea became very unmanageable, the stool assuming a thin grayish or greenish-gray, or yellowish, occasionally dark character. Free fat was never detected in them, though sought for diligently. Vomiting was also extremely distressing and constant, though often performed without nausea. Microscopic examination of vomited matters gave no information as relating to the nature of the essential trouble. They were largely made up of greenish mucus, often containing blood, or were often composed almost entirely of ingesta. Treatment, both of diarrhea and vomiting produced only temporary effect. There was complete anorexia. In spite of supporting and anodyne treatment the physical con-

dition steadily deteriorated, and on December 12 Professor Tiffany was called in consultation with a view to operative interference. While agreeing in the main with the diagnosis as given, Professor Tiffany in view of the general condition did not feel justified in operating. Diarrhea, vomiting and paroxysmal pain now became very distressing and the patient was kept constantly mildly under the influence of morphin, hypodermically administered. The tumor remained hard, irregular, and gave no sign of fluctuation. Tympanitis had noticeably increased on the 14th, and upon that date a noticeable fall of evening temperature was observed, but there was no increase of abdominal tenderness, though paroxysms of pain were frequent and severe whenever the effects of the morphin became weakened. On the 16th, cough developed and crepitation was heard at the base of the right lung. On the 18th at 8:45 o'clock she became very weak, the face, feet and hands cold, the respiration slow. She rallied slightly after a while and during the day had four dark green stools. On the 19th, at 9:45 o'clock A. M. she passed a copious stool consisting entirely of bloody pus. During the day she had several similar stools. At the same time the tumor became indistinct and noticeably smaller. She sank rapidly and died in collapse at 5 P. M. The course of the pulse, temperature and respiration and the extent of diarrhea are shown in the accompanying chart, which, however, dates only from the fifty-eighth day of the disease.

Post-mortem examination, by Dr. K. B. Batchelor, twenty hours after death. (Examination of abdomen only.) Abdomen distended and tympanitic. On opening abdominal cavity a large quantity of foul-smelling gas escaped with something of an explosion. Gas continued to escape for some seconds. Greater omentum contained a quantity of fat. There are multiple fresh adhesions between omentum and parietal peritoneum in superior portion of abdominal cavity, and there is also, here, very slight congestion in peritoneum. No fluid in peritoneal cavity. The adhesions (fine fibrous bands) are easily broken down and separated in right superior portion of omentum and peritoneal cavity. Toward the left side they gradually increase in number and size, but are easily separated everywhere.

Areas of fat necrosis are found in great numbers in left upper side of omentum, over the abscess cavity. None are found on right side. The inferior portion of omentum is free from adhesions or fat necrosis. The posterior surface of the omentum and the transverse meso-colon are much congested and covered with recent fibrous adhesions. The intestines in superior portion of abdominal cavity are tied together by numerous fresh adhesions. They are easily separated.

Stomach shows nothing abnormal. The head of the pancreas is almost entirely obliterated, the part remaining forming a portion of the posterior wall of the pus cavity. This cavity occupies the position usually occupied by the pancreas, together with the whole of the lesser omental cavity. Its walls are shreddy and have a spongy, worm-eaten appearance. The cavity extends upward behind the stomach to the vault of the diaphragm, the inferior surface of the diaphragm being covered, to a less extent, with the shreddy and spongy lining of the pus cavity. Situated about the center of the lower portion of this cavity is a small remaining part of the pancreas. It

has, heretofore, been wellnigh impossible, it may be hoped reasonably, that the more definite knowledge of their clinical history and symptomatology that we now possess will insure its very much more frequent recognition. The case that I have the honor to report presented characteristics that rendered an accurate diagnosis fairly easy to any one reasonably familiar with recent literature upon the subject. More exact acquaintance with acute pancreatitis, however, will probably reveal frequent inter-relations of all three varieties mentioned. My own case, for example, presented indisputable proofs of an antecedent hemorrhagic condition, as shown in the presence of blood cells and coloring matter in the contents and walls of the abscess cavity.

### STRABISMUS AS A SYMPTOM, ITS CAUSES AND ITS PRACTICAL MANAGEMENT.

Read before the Michigan State Medical Society, June 7, 1895.

BY LEARTUS CONNOR, M.D.

DETROIT, MICH.

Landolt in his classical work says: "A strabismus operation, when undertaken without an exact knowledge of the optical and muscular functions of the eye, is but a rude and dangerous experiment." The reason for this statement springs from the fact that strabismus is merely a symptom of numerous pathologic and congenital defects, and its rational management calls for the study and removal, or correction of these, so far as is practicable. The story of strabismus well illustrates the persistency by which the profession traces a symptom to its origin, in order that its cause may be removed and the symptom cured. Failure of squint operations has led to such study as revealed the reasons for the past defects and the methods for future success.

At present we know that some cases of squint are readily curable, that some are incurable, and others doubtful, calling for additional study ere they can be classed either as curable or incurable. Diefenbach operated first for convergent squint in 1839, by dividing the belly of the internal rectus muscle. His operation was based upon the analogy of operations upon contracted muscles in other portions of the body. He reasoned, that since division of contracted muscles or tendons elsewhere, restored muscular equilibrium, it should do so in the ocular muscles. He neglected to note that the problem of contracted ocular muscles differed radically from that presented elsewhere, in that opposing recti and their associated elastic tissues constantly tended to separate their divided ends. Hence the results obtained by himself and others were so frequently disappointing and actually disastrous that, except for the radical change introduced by Bohm, the operation must have passed into merited oblivion. This transferred the site of the operation from the belly of the muscle to its tendinous insertion, thus leaving the capsule of Tenon mainly undisturbed. The technique of the operation was so perfected by von Graefe as to render it easy and safe of performance; especially useful was his method for either increasing the effects of a tenotomy or diminishing the same.

The ophthalmoscope enabled us to see that some cases of squint were due to diseases of the refractive portions of the eye, distorting the passage of the rays of light in their course to and from the retina, or, as in case of disease of the optic nerve, cutting off

the power of transmitting the impression made by the rays of light upon the retina, to the brain.

Not a few cases were traced to corneal opacities. Eyes entirely blind were found to often squint. Thus the symptom squint was traced to a variety of pathologic conditions, having one common feature, viz., they rendered the vision of the two eyes unequal and so deprived them of the "guiding sensation." With these facts in mind it is clear that a squint operation, without previous careful ophthalmoscopic examination, must be "a rude and dangerous experiment."

Donders' studies of refraction and accommodation traced this symptom to other and more common sources. Thus he showed that three-fourths of the cases of convergent squint were hyperopic, and an equal proportion of the cases of divergent squint were myopic. He also pointed out the intimate relationship between convergence and accommodation, a physiologic fact which anatomic researches have supported, by demonstrating the close relation of their centers in the floor of the fourth ventricle. When the eyes accommodate for near objects by the contraction of the ciliary muscle, they also converge by the contraction of the internal recti. The bearing of this fact upon the causation of squint is apparent, when it is remembered that the hyperope is compelled to accommodate at all distances, and so the ciliary muscles are in a state of constant tension, and with them the internal recti. The flattened eyeball of the hyperope has broken the harmony which should exist between convergence and accommodation. Thus, if the hyperope accommodate for twelve inches, as in reading, the convergence will be at a point less than twelve inches if the muscles are of normal power. The result is a diffusion of impressions upon the retina, to escape which the squinting hyperope turns one eye in and fixes the other at twelve inches, ignoring the impression of the squinting eye. A repetition of such acts forms a squint habit, which, while at first alternating, at last usually becomes fixed. The habitual suppression of the image in the squinting eye is followed by a loss of the power of perception—a loss which can be repaired if the retina be normal at the first. Thus we have convergent squint due to eyes defective in the length of their antero-posterior axes. To the query, Why all hyperopes do not squint, it is replied that in those who do not squint, the normal balance between the power of the internal and external recti is so changed that, instead of being 4 to 1 it is less, only 2 to 1 or even 1 to 1. Hence in the non-squinting hyperopes, the excessive convergence required for distinct vision is balanced by the weak interni, so that the eyes remain straight. If the externi be much in excess of the interni, we have a hyperope with divergent squint. In support of this view of the causation of squint, advanced by Valk, I have habitually found all hyperopes to have weakened interni, as measured by the standard of 4 to 1.

Donders found that myopes needed little or no accommodation, because the eyeballs were already too long; hence the convergence in near seeing would be *nil*, and so if the strength of the recti was normal, the eyes would turn outward and give a divergent squint. But if the externi were weak the eyes might remain straight, or if very weak they might turn in and give a convergent squint. Aside from muscular action in causing divergent squint in myopes, we

have the elongated antero-posterior shape of the eyeball; the greater distance between the temples of myopes; variations of the orbital fat, and of the attachments of the ocular muscles to the bony walls.

These studies in refraction, accommodation and action of the external muscles of the eyes have led to far reaching consequences in the management of the symptom of squint. Thus it has shown that some cases of convergent squint can be permanently cured by the wearing of such convex glasses as fully correct the abnormal flatness of the eyeballs; that some cases of divergent squint can be cured by the wearing of concave glasses, which reduce the refractive power of the eyes to their normal standard. The symptom disappears when we have restored the lost equilibrium between the refraction, ciliary and recti muscles.

As the nature of mydriatics became understood, it was found that their use in paralyzing the accommodation, permitted the recti to assume their normal functions, and so facilitated a cure of cases in which the squint persisted after the defects of refraction had been corrected by appropriate glasses.

Statistics on a large scale, show that while tenotomies and advancements cured many cases of squint, the intelligent correction of refractive defects and the use of mydriatics cured many additional cases, added to the number of those who secured binocular vision and diminished the number of divergent squints following tenotomies. Thus by distinct lines of evidence we have traced the symptom squint, in many cases to defects of refraction, and abnormal ocular muscles. This result is still further confirmed by recent studies of those similar disturbances of muscular equilibrium known as insufficiencies or heterophorias. These studies have encouraged surgeons to seek binocular vision in the management of squint, rather than rest content with the straightening of the eyes, because they have given us finer and more precise methods of operating and more suitable instruments, both for determining the muscular disability and for doing the operations; in short, they have furnished us with a micrometer adjustment for the doing of squint operations, and so raised them to a higher perfection.

Finally, squint has been traced to a defective structure of the retinal percipient elements, congenital in its origin, unchangeable in character, and causing an inability to see other than large objects. Upon these eyes, neither glasses, atropin, or tenotomies have other than a cosmetic effect; only operative procedures avail aught in their management.

Having collected all existing knowledge respecting squint, we see still vast fields, uncultivated fields adequate for the surplus energies of more than a generation of physicians. Thus we want a comparative study of the origins and insertions and other relations of the ocular muscles; the modifications of their activities by the varied shapes and sizes of the eyeballs, by the individual peculiarities of the capsule of Tenon, by the quantity and quality of the orbital fat or the fibrous stroma which holds it in place. We want a comparative study of the orbital walls, as bearing upon their contents, and the functional activities of the eyes. We have still much to learn of the nervous apparatus of the eye and its muscles, of its visual and motor centers, and of the complex relationship of this apparatus to other organs; in fact, time fails us to even enumerate the

fields awaiting investigation, in their relation to the causation and management of squint. However, our present knowledge enables us to attain very satisfactory results in an increasing number of cases. It is a marked advance in that we aim, not only to straighten eyes, but to have the patient possess binocular vision. This is attained by supplementing the operations for squint with gymnastic exercises, innervation treatment or partial tenotomies, until we have enabled the eyes to fix upon any point within the visual field. This necessitates a cordial coöperation of physician and patient during an extended period, varying with individual cases.

For convenience, the management of squint may be divided into operative and non-operative. The operative measures are tenotomies of the stronger muscles or advancement of the weaker ones; both of which may be needed in the same case.

The non-operative means are:

1. Careful attention to the patient's constitutional condition.

2. The correction of all defects of refraction, so far as these affect the squint unfavorably—the correction to be made from data obtained while the eyes are fully under the influence of atropin.

3. The continued use of mydriatics.

4. The use of gymnastic exercises, or the innervation treatment of Gould, to increase the power of the weaker muscles, or to bring them into coöperation with the stronger.

In each case the surgeon is met with the question, Is this an operable one? To aid in answering this, I give brief extracts of four typical cases, whose condition I was able to record many years after the treatment—affording the final results of the management of convergent squint:

*Case 1.*—Boy aged 5, strong, with marked convergent squint of the left eye, noticed when six months old. An examination with the ophthalmoscope showed a healthy ocular media; vision of right eye was 20-20; of the left 20-200. Under a mydriatic the ophthalmoscope showed a hyperopia of a dioptric and a half. The full correction of this was prescribed, and the ciliary muscles kept fully under the influence of atropin, but at the end of six months the result was negative. The internal rectus tendon was now divided and the other treatment continued, with the final result of leaving the eyes perfectly straight, but with no improvement of vision even fifteen years after the tenotomy. This was clearly an operable case, as nothing but the tenotomy changed the squint, and even it failed to improve the vision. Such cases are defective in the percipient elements of the retina of the squinting eye, or its optic nerve relations.

*Case 2.*—A healthy girl aged 9; convergent squint of right eye since 1 year old, at first alternating but finally fixing; the ophthalmoscope showed perfectly healthy media, in both eyes, and a hyperopia of two dioptics in the right eye and one and a half in the left; vision of right eye was 20-200; of left eye 20-40. Full mydriasis and correction of hyperopia failed to benefit the squint, so that a tenotomy of the right internal rectus tendon was done. This failing, a month later the left internal rectus tendon was divided, with the result of making the eyes practically straight and after many months bringing the vision of each eye to 20-20. These two cases were alike in both requiring ocular tenotomy, but unlike in that the vision of the first was unimproved, while that of the second became normal, though the same methods were employed. The first represents a class of cases, congenitally defective in the percipient elements of one eye and so incapable of development; the second stands for a class in which vision is lost by non-use, but can be restored if the eye can be placed in such relations as will admit of the normal exercise of the retinal elements.

*Case 3.*—Boy aged 5; squint noticed when 2 years old; alternating then and at examination; vision of each eye 20-40; hyperopia two dioptics, the correction of which gave a vision of 20-20, and rendered the eyes perfectly straight.

Atropin was used six months and the correcting glasses worn constantly, with the result that ten years later the eyes were straight and the vision binocular and normal.

*Case 4.*—Boy aged 8; convergent squint of the left eye, noticed when year and a half old as alternating but now fully fixed; ophthalmoscope revealed perfectly clear media, and a hyperopia in the right eye of two dioptics, and in the left of two and a half; vision of right eye 20-30; of the left 20-100. Glasses correcting the hyperopia, both straightened the eyes and substantially improved the vision of the fixed eye. This improvement continued till vision of the squinting eye was equal to that of the other, and nine years later the vision continued normal and the eyes perfectly straight.

The last two cases were clearly non-operable. True, a tenotomy would have rendered the eyes straight, but later they would have diverged.

To avoid complexity, simple hyperopic cases are selected, but cases of hyperopic astigmatism, simple or complicated with hyperopia obey the same laws.

It follows that in every case of uncomplicated squint, the question arises, Does it belong to the class of congenital amblyopias or no? If the answer be affirmative, the case can be operated upon at once for cosmetic effect—there being no hope of improving vision. If the answer be negative, we must separate the operable from the other cases. The following has been found a safe method of procedure:

1. Eliminate all cases of paralysis.
2. With the ophthalmoscope, detect all squints due to opacities in the refracting media and treat them by operations, as in congenital amblyopias, for cosmetic effect merely:
3. Determine the vision of each eye, and the kind and degree of ametropia under mydriasis.
4. Correct the full amount of ametropia, and if this renders the eyes nearly or quite straight, an operation is inadmissible and the cases will probably go on to full recovery, under the use of glasses and atropia.
5. If glasses and atropin produce no perceptible effect upon the squint, then a tenotomy of one or both recti is indicated, followed by the use of glasses to relieve the eye strain and retain the eyes in the position resulting from the operation. The securing of binocular vision in this class of cases is materially aided by gymnastic training of the weaker muscles, and the coöperation of all.
6. The time for operating upon convergent squint depends entirely upon the ability of the surgeon to separate the operable from the non-operable cases. An operable case is best treated as early as the coöperation of the patient can be assured—usually at about 6 years.
7. If glasses correcting the full ametropia be worn at an early date, the normal relations of convergence and accommodation are soon established, better developed during child growth, and the ultimate vision more perfect.
8. To secure the best results, calls for much attention to the management of these cases, during a period extending over months or even years.
9. As to the final balance of the internal to the external recti, a proportion of 4 to 1 has given the greatest comfort to patients, and the best vision under all circumstances.

#### CONCLUSIONS.

1. Strabismus is always a symptom of some morbid or congenital defect.
2. Success in its relief, has increased in direct proportion to our knowledge of these conditions and defects.

3. Strabismus due to opacities of the refracting media or to congenital amblyopia, can only be treated by operations, and solely for cosmetic effect.

4. Strabismus due to the combined action of hyperopia and normal recti, is treated by tenotomy or advancement, atropin mydriasis, suitable glasses and gymnastic or innervation exercises.

5. Binocular vision is to be sought for in all cases other than those due to opacities of the refracting media, congenital amblyopia or organic disease of the retina or optic nerve. With sufficient perseverance, it is attainable in a fair proportion of cases.

6. Recent studies of heterophorias afford substantial aid in the better management of squint, by the new standards of both operative and gymnastic work, by the more convenient and reliable instruments for examination, and finer ones for operation.

7. There yet remain a number of cases of squint not explicable by our present knowledge, or amenable to treatment by accepted methods. To bring these under definite law, both as to cause and management, remains for the student of ophthalmology.

103 Cass Street.

#### CONSERVATIVE BRAIN SURGERY.

BY S. V. CLEVENGER, M.D.

CHICAGO.

In "Lectures on Intracranial Surgery," published in this JOURNAL, June 8, 1895, by Dr. Emory Lanphear, certain statements are made that are not warranted by pathologic and alienistic knowledge, certain operations are recorded as having been performed that are not justified by the literature or experience of those most competent to judge; and the results of the operations being unfavorable, and in some instances causing death, the conclusions of the paper alluded to are improper, and if recklessly absorbed and acted upon by others may be productive of further discreditable surgical interferences, and revolt of the laity against "butchery," as many unsuccessful operations are styled, even when these are judiciously and justifiably done.

That Dr. Lanphear is a "brilliant operator" is well known, but when this ability is unassociated with other requisites it is like pyrotechnics near a powder magazine. He speaks of "insanity from softening of the brain." He can not find such an expression in any work on insanity worthy of the name. At this date, to speak of "softening of the brain" as any kind of insanity, would place the physician who used the term upon the level of the public, untrained in any kind of medical information. "Softening" is not an initial lesion, but merely a consequence, and where found associated with cerebral defects, mental, motor or sensory, it is subsequent to hemorrhage, compression, contusion, plugging of arteries or veins that originated such defects. Extensive softening may exist without insanity, and often, when found in the brains of the insane, is not related to the insanity in the remotest degree.

Trephining to relieve compression of a cortical, or even to reach a reasonably accessible subcortical neoplasm, either of meningeal or neuroglial origin, or to raise a depressed piece of bone, or remove an exostosis, or to evacuate an abscess that can be reached without running the risk of murder, no one should find fault with, but when it is proposed to open the brain for an embolism situated usually near the cerebral base, most often in some Sylvian artery branch,

an embolism that may be resorbed if nothing whatever is done, is surgery worthy of the Middle Ages.

Dr. Lanphear is surprised that he "can find no published reports of operations for epileptic insanity," and supplies the void by telling of two cases operated upon by Dr. A. B. Shaw, both of which availed nothing. This operation for "insanity from softening of the brain—complete relief," describes an aphasic who had a few symptoms of traumatic insanity and who consented to the operation. "He was discharged in excellent condition, mentally and physically." It is too bad that no statement of his *present* condition three years after the operation is afforded us. It is safe to assert that, if living, the patient is worse than before the interference, not necessarily from the operation, but from the natural unrelieved course of such derangements.

The Doctor quotes an author whose reputation is quasi-scientific and popular—Maudsley, on the "Pathology of General Paresis" (paretic dementia): "Morbid adhesions of inflammatory origin, slowly spreading between the cortex and its investing membranes," and says: "If, then, by surgical means, we can arrest the spread of the trouble while it still involves that part of the brain which presides over," etc., etc. Ten years ago Spitzka, in his "Manual of Insanity" elaborated the pathologic anatomy of paretic dementia, and such conditions as Dr. Lanphear quotes from Maudsley are not mentioned, but other things are, such as intense degenerative processes in the brain and cord, pial adhesions to the cortex, cystic degeneration of the cortex, sclerosed and obliterated blood vessels, granular change in the ventricle endyma, the nerve cell degeneration and formation of the "spider-shaped cells of Meynert," the most constant and intense changes being in the *pons* and *medulla oblongata*, sclerosis of the cortical vessels, kinked, distorted, aneurysmal, plugged vascular channels, and, in short, "there is scarcely a ganglion or fiber tract that may not be affected." (Spitzka p. 228). Or, take the older English work of Mickle, "General Paralysis of the Insane," with the specified individual autopsies showing extensive general brain alterations, and the quotation from Maudsley becomes insignificant as a pathologic suggestion for cerebral surgery; as well attempt the diversion of Niagara River by opening a faucet.

Remember, also, that remissions of weeks or months and, in extremely rare cases, of years, have occurred in paretic dementia histories, and the temporary improvements after operations in a few cases may be accounted for. The reduction of one case to dementia proper by trephining can scarcely be called a success, for such an interpretation we can place upon Rey's case, which "afterward remained calm and quiet." . . . "The subsequent history is unknown." One can be "quieted" with a brick. In another, "there was great improvement but the patient died in six weeks." In this case there was *cerebral atrophy*. How could trephining be expected to relieve atrophy of the brain?

As for syphilitic insanity, common sense would suggest a fair trial of K. I. before operating to relieve gummatous membranes. He says: "Manifestly, some of them can be readily removed by the knife." But how about those which can not?

Under the head of "syphilitic insanity," the Doctor narrates an epileptic insanity case, not considering that both these psychoses have separate and dis-

tinct clinical peculiarities. The operation "was characterized as a gross outrage" by the asylum physician; the patient died nine months afterward. "Had an operation been performed upon the right side of the head, subsequent to the one upon the left, the probabilities are that cure might have resulted." By what reasoning does Dr. Lanphear arrive at this conclusion? If removal of the "greater portion of the left parietal bone" was not sufficient, why, in the absence of any focal indications should the right also be removed, any more than the frontal and occipital? Unchecked, unchallenged, our "brilliant operators" will be removing the temporals and sphenoids next.

The quotation from Horsley is misapplied. Remove an affected area by all means, if well made out by focal or other definite symptoms to be in an accessible part, but for diffuse syphilis of the brain, or idiopathic epilepsy, in most cases, it is little short of homicide to attempt cerebral surgery where the operation becomes but an aggravation of inflammatory or allied states, beyond reach, as multiple gummata are likely to be.

Burkhardt's six cases of paranoia are cited. A fanciful psychology of the association paths of the brain was invented to warrant the cutting. "Ideogenic areas" are familiarly mentioned as though definitely localized. "A portion of the frontal and parietal lobes before and behind the ascending convolutions were removed with very satisfactory results in one case." What the "very satisfactory results" were, are not mentioned. "The other died from convulsions on the sixth day." "Satisfactory results" were obtained in three other cases. In one, "recovery from the paranoia was perfect."

The imperfect record in most of these cases, the ambiguity as to the effects of the operations, the neglect of detailed accounts of the condition of the patients for any period, short or long, after the surgery, and the general "altogetherness" the *tout ensemble*, reminds one of "Alice in Wonderland" narratives, written to startle and entertain, rather than to contribute seriously to science.

The Doctor's twelve rules seem to have been hastily written. The importance of the errors in them make it necessary to call attention to the dangers of following such blind leadership.

#### "RULES FOR TREPHINING FOR INSANITY."

"1. Every depressed fracture of the skull should be subjected to operation at the time of the accident, regardless of the amount of depression and irrespective of pressure symptoms."

This rule might apply to any case of obvious fracture. Insanity is rarely demonstrable immediately after a fracture of the skull.

"2. Every case of prolonged unconsciousness following a blow in the frontal region should be trephined for exploratory purposes; upon both sides, if necessary."

How long is "prolonged?" Ordinary cerebral concussion may be attended with prolonged unconsciousness and the occipital region may be injured by a frontal blow. It might be brilliant to trephine over *contre-coup* locations. The removal of the entire skull would be thoroughly exploratory.

"3. The skull should be opened in all cases of insanity dependent upon trauma, at the earliest possible moment after development of the mental symptoms."

Symptoms usually develop in such cases many years after the injury. Should the mental part of the brain be opened up, and if so where is it? When insanity supervenes from trauma the brain, in the vast majority of cases, has undergone permanent change without definite localization. What good would opening the skull do, aside from making a fee?

"4. Operation is justifiable in every case of serious suspicion of tumor, abscess, or softening of the frontal (or any other accessible) region."

*Set*, with the exception of the word "every," which is too sweeping.

5. "Operation is advisable in every insanity following cerebral or meningeal hemorrhage in which localization is possible, the clot accessible and the mental trouble of recent development."

Such combinations are extremely rare, and there is nothing in medical or surgical literature to cause enthusiasm over trephining cases of cerebral hemorrhage. The suspicion attaches that death has been precipitated by many such operations, while expectant treatment has been rewarded by a fair number of recoveries, and a large number of partial recoveries. Sometimes the operation has restarted a deep-seated hemorrhage and the usual inability to differentiate cortical from basilar or subcortical and inaccessible recent ruptures of vessels make the operation exploratory, which, of itself, is adding to a trouble without reasonable certainty or assurance of benefit. The chances for aggravation by trephining outweigh the possibilities of relieving.

"6. Every case of insanity developing in the history of otitis media suppurativa deserves immediate exposure of the favorite site of cerebral abscess."

In fact, the simple operation of taking away the temporal bone or a large part of it. Exploration of the middle ear, the mastoid cells and a careful study of the case had better precede opening the temporal region. The bones may be found carious, an abscess may be evacuated in that neighborhood, but the chances are that an extensive meningo-encephalitis is the pathologic condition, in which case less harsh measures would be of more avail, and decidedly less dangerous.

"7. Trephining for the purpose of breaking up adhesions of an old meningitis has been successfully practiced though it is not to be strongly advised."

Particularly, if the meningitis is basilar or universal or even covering a large brain area. The mere matter of tearing off a few inches of cortex with the adhesions might have some attention. Certainty of a very circumscribed, easily accessible and small pachymeningitis offers chances for operating, but more study should previously be accorded the case than the rash operator indulges.

"8. Establishment of permanent drainage beneath the scalp is permissible in the beginning of a terminal dementia succeeding chronic hydrocephalus."

What earthly benefit can accrue from interfering with the brain, or even the scalp, of a terminal dementia, when the hydrocephalus is compensatory, the cerebral lobes shrunken, *atrophied*, *sclerosed*, every vestige of hope of return of reason vanished as though the head were cut off? The fluid merely fills the space between the shrunken brain and the meninges.

"9. Operation for epileptic insanity is advisable whenever there are symptoms pointing to a focal lesion."

This could apply to any Jacksonian epilepsy of cortical origin. Such instances are one in a thousand among the insane and the brain disorganization is too advanced to make it a warrantable operation. Observe the extravasations, the leucocytic exudates that have organized at the brain base, the universal heavy dense membranes and adhesions found in epileptic insane autopsies, and then, even with a focal lesion, which is not the only brain trouble, what hope is there from an operation?

"10. Experimental trephining in the early stage of general paralysis of the insane is considered worthy of further trial."

Every such experiment has been a wretched failure, beside too many cases of general paralysis of the insane (paretic dementia) have been improperly diagnosed as such. An alienist would feel like throttling an operator who cut into the skull of a maniac, whose chances of recovery are excellent, through mistaking his case for one of paretic dementia, which has been repeatedly done.

"11. Operation should be done for even a suspicion of the existence of a gummy deposit in the bone or meninges."

If gummata are in one area they are probably in another; a favorite site is about the pons and in the course of the sixth pair of nerves. The removal of a single gumma or group of gummas from one part does not check the disease. A vigorous saturation with K. I. would be all that is primarily warranted and particularly where only a "suspicion" of a gumma existed.

"12. The formation of fenestræ in the skull is permissible whenever there is evidence of intracranial pressure, even of unknown origin. "Sometimes cerebral pressure is from constipation. We have such articles as cathartics, ergot, iodid of potassium, and a neurologist might hit upon some other means of relieving intracranial pressure, if the term intracranial is meant in the sense in which we use the word intrauterine. In another intracranial meaning an exostosis, or what is sometimes improperly called an endostosis, may produce brain pressure and the fenestra might help, or it might afford an opportunity for hernia cerebri, which is scarcely desirable."

There is something in Lannelongue's craniotomy (not craniectomy) in cases of primary synostosis to allow the brain room to expand, and if surgeons would allow the alienist to select cases of idiocy and imbecility suitable for operation, instead of rushing into craniotomy with the average surgical unfamiliarity with the insanity, the percentage of successful results would undoubtedly rise. Where the brain has undergone permanent retrogradation, and of this the alienist is the best judge, there can be no hope from any treatment.

Imagine the resentment of the surgeon were some neurologist to venture advice in a case of intestinal resection, but the alienist has as good a right to feel insulted when a surgeon, who has but the most superficial ideas of psychiatry, promptly takes up his knife and trephine and proceeds to "cure" incurable demented, imbeciles, and other comparatively brainless unfortunates, without seeking advice from those who make such matters a life study. There are vast experimental fields left over from the last century in clitoridectomy, circumcision, rectus muscle snipping for insanity, in spite of the failure of the great Chicago "officialist" with his sphincter cut-

ting for mental and all other troubles, including baldness and corns, and notwithstanding the controversy between the State Board of Charities and another "officialist" who castrated a lunatic now in the Elgin Hospital for the Insane.

Castration, oöphorectomy, sphincter, and ocular rectus muscle cutting, clitoridectomy and other reflex pleasantries, can earn fees at less risk to the patient, just as well as brain surgery with inferior knowledge of psychiatry and cerebral pathology, even when performed by a "brilliant operator."

70 State Street.

## THE AURAL MASSEUR IN THE MANHATTAN EYE AND EAR HOSPITAL.

BY CHEVALIER JACKSON, M.D.

PITTSBURG, PA.

The aural masseur described by me in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of May 11, 1895, had given me such good results in the treatment of defective hearing and tinnitus aurium, in cases of otitis media catarrhalis chronica, that I sent an instrument like my own, some six months ago to Dr. D. B. St. John Roosa for a thorough trial and opinion on its merits. He placed the instrument in the Manhattan Eye and Ear Hospital, where it was tested thoroughly in charge of Dr. Bretano Clemens who has sent me the following report:

I submit to you some results of my observations of the use of your electro-pneumatic masseur in cases of tinnitus aurium. Of late years so many instruments have been brought to the notice of the profession for the relief of this distressing affliction, and the advantages of each have been so strongly maintained by their various supporters, that I undertook the task of ascertaining the special field of usefulness of your masseur with some prejudice against it. The relief obtained in a number of cases in which other known methods and remedies had failed, however, has convinced me of the merits of the instrument, and of the correctness of the principle upon which it is founded. My tests of it have been made in all classes of cases of non-suppurative ear disease associated with tinnitus aurium, viz., otitis media catarrhalis chronica, including, the hypertrophic and the atrophic forms; disease of the auditory nerve, and in the mixed form where the sound-conducting and sound-perceiving apparatus are simultaneously involved. It will be seen from the details hereafter given, that some cases were more promptly benefited than others, and that in a few, the tinnitus was so much intensified that further use of the method was out of the question.

In applying the instrument, I was particularly cautious not to depend upon a patient's statement that the machine was "working," but by substituting the pneumatic speculum of Sieglé for the ear tip you sent with the masseur, I could distinctly observe the movements of the membrana tympani and malleus to my entire satisfaction.

The usual hyperemic conditions observed after using the Delstanche masseur, I have never witnessed after an application of your instrument.

Premising, that upon the whole, the use of your instrument has demonstrated its value to my mind, the following are the details of a few cases which I

have been able to observe, and which will serve to facilitate the further study of its application:

*Case 1.*—Male, physician, aged 55. Applied for relief of tinnitus on Feb. 5, 1895. History: distressingly loud tinnitus, like escaping steam, and distressed for past ten years; occasional attacks of vertigo which are slight; plethoric, and unsteady in walking. Objective examination: both membranes very opaque, some retraction and hyperemia along the malleus handle.

Tests: watch R., 0-60; L. 0-60; whispered voice R. 0. L. 0; no improvement after inflation. Absolutely no bone conduction for forks C1, C2, C3 and C4. C fork was perceived only for an instant. Slight aerial conduction of low tones only.

This patient had been treated by many famous otologists of this country, but derived no benefit from their efforts. Removal of the ossicles was advised several times, but absolutely refused. The masseur was used with no effect for several weeks, applications being made tri-weekly, but on March 15 he reported with much glee that the noise had suddenly left him the night before for the first time in many years, and remained away for twenty-four hours. He is much improved; the noises though present, are not distressingly loud. This treatment was continued for several weeks longer, and he then departed for Augustine, Fla., much better and freer from tinnitus than ever before.

Six cases similar to the one quoted have been much benefited, the tinnitus becoming intermittent or remaining continuous with less intensity.

*Case 2.*—O. M. C. C. Female, aged 22, general housework, applied for relief of tinnitus aurium and deafness on Feb. 28, 1895. History: deafness principally in left ear, for past two years and rapidly growing worse. Tinnitus constant, and of pulsating variety, intensified by recumbent position. Deafness right ear for past two months—tinnitus ringing, not constant. Hears better in quiet place. Objective examination: right ear, membrana tympani cloudy, dull, and slightly retracted. Left ear, membrana tympani very much retracted, so that the malleus handle is nearly horizontal; cloudy, slightly hyperemic. Sieglé shows malleus to be rigid. Nose: rhinitis hypertrophica chronica. Luschka tonsil slightly enlarged. Eustachian tubes closed.

Tests: watch R., 5-60 after catheterization 12-60; L., c-60, after catheterization, 3-60. Right ear, C, 23-21; C1, 18-10; C2, 28-20; C3, 18-10; C4, 25-12. Left ear, C, 8-25; C1, 8-12; C2, 15-25; C3, 13-10; C4, 15-10.

Treatment; Eustachian catheter and menthol vapor. The pneumatic masseur was used, but each application increased the intensity of the tinnitus in the left ear, to such an extent that further use of it had to be discontinued.

In another case, exactly similar to the one first quoted, the result was equally unfavorable after using the masseur. Therefore, in twenty-two cases of otitis media catarrhalis chronica, associated with tinnitus aurium and treated with your masseur, two cases were unfavorably influenced, and twenty more or less benefited.

The following brief report will show how quickly relief follows the application of the masseur in some cases of O. M. C. C.:

*Case 3.*—Female, aged 35, servant; came to the hospital on Jan. 15, 1895 for treatment. History: deafness followed an attack of scarlet fever fifteen years ago, and is gradually growing worse. Tinnitus aurium in right ear. Hears better in noisy place. Objective examination: right membrana tympani moderately retracted, cloudy. In left ear the local appearances are similar.

Watch R., 12-60; L. c-60. No improvement after inflation. Whispered voice, right, three inches; left whispered voice, six inches. Forks: right C, 0-33; C1, 5-11; C2, 14-23; C3, 8-12; C4, 10-8. Left C, 15-33; C1, 7-12; C2, 16-21; C3, 12-12; C4, 15-8. Vertex test heard better in left ear.

Treatment: the electro-pneumatic masseur relieved the tinnitus at once. After three applications the noises disappeared, and have not returned up to the present time. The deafness remained uninfluenced.

## MIXED CASES.

*Case 1.*—Female, aged 46; first came to hospital April 19, 1894, for treatment. History: deafness for past fifteen years, gradually increasing; hears better in a quiet place; considerable tinnitus aurium in both ears, which is always much increased during an attack of acute rhinitis. Objective examination: both membranes much thickened, slightly hyperemic and moderately retracted.

Watch R, 0-60, slight increase after catheterization. Left 0-60, after politization, 0-60. Whispered voice R. E., three inches. Whispered voice L. E., two inches. Vertex test (Weber) heard better in right ear. Forks: right, C, 14-11; C1, 10-4; C2, 26-0; C3, 8-0; C4, 6-0. Left, C, 13-8; C1, 7-4; C2, 25-0; C3, 7-0; C4, 8-0.

Nose: rhinitis hypertrophica chronica. Tubes closed.

Treatment: the Eustachian catheter, menthol vapor, and an occasional passage of an Eustachian bougie, with the use of the Delstanché masseur, which was employed for six or seven months, with but indifferent results.

Three months' use of your pneumatic masseur gave only transient relief from the noises. On March 21, 1895, the tinnitus was louder than ever before since being under treatment. She had taken fresh cold. On April 4, 1895, she reported considerable improvement, and on the 13th, that the tinnitus disappeared from right ear entirely, it remaining in the left, but very feebly. Tuning fork tests were made on April 13 with following result:

Right, C, 7-10; C2, 10-0; C4, 8-0; Left, C, 8-11; C2, 0-0; C4, 8-0. Watch, right, 1-60. Left, 0-60. Right, whispered voice, eight inches; left, ten inches. The masseur treatment will be continued.

*Case 2.*—Female, aged 40, housekeeper, first came to hospital for treatment Jan. 22, 1895. History: afflicted with deafness and tinnitus for many (?) years. Three weeks ago took a heavy cold, and has been growing rapidly worse. Tinnitus principally left, constant and whistling. Objective examination: membrana retracted and very cloudy. Sieglé demonstrated no ankylosis of hammer. Chronic follicular pharyngitis, tubes closed.

Tests: left ear, watch 0-60, after catheterization 0-60. Whispered voice two feet, after catheterization two feet. Vertex test (Weber) heard equally well in both ears. Fork test: left C, 12-15; C1, 10-5; C2, 10-3; C3, 8-4; C4, 12-4. Treatment: electro-pneumatic masseur and Eustachian catheter. Two days later reports that the tinnitus is exactly the same; the masseur only gave relief for eight or ten hours. Four days later, much improved, the tinnitus remaining away for a longer period after each application.

This case gradually improved and finally ceased attending the clinic. Ten cases corresponding to those quoted were treated with varying results. Some were promptly benefited, while others only experienced amelioration from the existing tinnitus.

A. The electro-pneumatic masseur affords relief to many patients suffering with tinnitus aurium. How permanent this relief may be, must be determined by more extended observation.

B. The use of the instrument is apparently contraindicated in cases where the existing retraction of the membrana tympani and malleus causes an increased intra-labyrinthine pressure.

## CIVIL SERVICE REFORM IN STATE INSTITUTIONS—REORGANIZATION OF THE MEDICAL STAFF.

BY BOERNE BETTMAN, M.D.

PROFESSOR OF OPHTHALMOLOGY AND CLINICAL OTOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS; PROFESSOR OF OPHTHALMOLOGY IN THE POST-GRADUATE MEDICAL SCHOOL; PRESIDENT OF THE ILLINOIS STATE BOARD OF CHARITIES, CHICAGO.

All measures toward reform in the treatment of the insane will prove an utter failure until the manner of appointing the medical staff is radically changed.

The superintendent and head of the institution must possess not only the requisite medical skill to fit him for the care and supervision of the patients

intrusted to him, but he must also be endowed with executive abilities to maintain a business-like organization and to exact well-disciplined service from a large *personnel*. Burdened as he is by multitudinous duties, he naturally is obliged to delegate the treatment to the medical assistants. To them is intrusted the diagnosis of the mental complaint and its subsequent treatment. Upon them rest great responsibilities.

Medical assistants are ordinarily appointed through political or other influences. The superintendent is often not consulted in the matter, but is forced to submit to the dictates of others, whose only concern it is to obtain a job for some influential friend. Persons absolutely unfit, both by education and character, are thus thrust upon the institution, to the detriment of its insane inmates.

The number of physicians in our State asylums is inadequate; one for every four or five hundred patients. It is commonly acknowledged that one medical man should take care of no more than two hundred. Routine and careless treatment is thus avoided. The individuality of each case can be more readily studied. The now over-burdened physician has but little time at his disposal for further improvement and recreation.

The isolated position of the asylums is another source of danger to the medical mind. Far distant from medical centers, cut off from associations with scientific men, deprived in this matter of the stimulus necessary to further improvement and original research, his ardor is either allowed to lie dormant or absolutely to die out for want of encouragement.

A laboratory well equipped exists in but one of our State asylums. Its value can not be over-estimated. It is a necessary adjunct. The practical results obtained in medicine are the outcome of the applications of scientific research and investigations. The latest improvements in surgery were only possible after the untiring labors of a Pasteur and Koch. The cure for diphtheria and hydrophobia depended upon the cultivation of bacteriology. Practitioners have neither the time nor the special qualifications to devote to strictly scientific pursuits. A specialist is necessary. A pathologist well trained and endowed with the proper zeal is needed for this work. His presence will also have a stimulative effect on the medical staff. If ambitious, he will imbue others with such a spirit for earnest and conscientious work that enthusiasm will be awakened. No individual can perform labor creditably unless he is devoted to his vocation. This is especially true in the calling of a physician. Constant and untiring research is an especial feature of his life. Science is ever making such rapid strides that to keep abreast of the times requires uninterrupted study.

To remain at a standstill means stagnation, deterioration. The introduction of staff meetings, for the purposes of consultation and discussion of medical themes and analysis of cases, will also call into life, taste for more thorough examinations of and conscientious devotion to the patients. These various reasons induced the State Board of Charities to issue a circular letter to the trustees of the four State asylums requesting them, in order to improve upon the present methods, to appoint for each hospital a pathologist and a number of internes.

General hospitals the world over, have for years given recent graduates of medicine an opportunity to

get a practical knowledge of their profession by employing them as assistants to the medical staff. Residing as they do in the hospital, and being called upon to perform certain services to the sick, under the supervision of the physician in charge, they obtain ample opportunities of acquiring useful knowledge and of profiting by the experience of their older and better informed superiors. The patients, on the other hand, have constantly at hand well educated assistants who are intelligently carrying out whatever orders may be given by the attending surgeons. This system of internes is doubly beneficial. Again, a certain amount of routine clerical work, as writing up the history of the patients, keeping daily record of their condition, etc., is performed by the interne, and relieves the attending physician of useless and unimportant labor, giving him time for more important work and self-improvement.

The appointment of internes must be absolutely free from prejudice and preferment of all kinds. The ablest only are worthy of these positions, for they alone are capable of profiting by the advantages allotted to them. They only possess the qualifications which will insure earnest effort and arouse a desire for progress. These competitive examinations should be free to all senior medical students of medical schools in the State of Illinois and to all Illinois practitioners of not more than five years' standing. Those senior students who succeed in obtaining sufficiently high marks to become internes should only then be accepted as such, after having received their doctor degree from their respective colleges. The closing of the college year varies in different institutions. To induce a sufficiently large number of students to compete, before returning to their homes, the examinations should be held before May, and the successful candidates be assigned to their duties a few months later, after the final college examinations have taken place. All efforts should be made to place the examinations on a strictly impartial footing. The internes should receive beside their board and lodgings, a small monthly salary. They should be expected to serve at least one year, and be permitted to fill vacancies occurring in the staff of assistants. This system, if rigidly enforced, will be one step toward the introduction of a system of civil service reform in the medical corps of our institutions, which can only be associated with the highest benefit to all parties concerned. It will secure for the State a perfect medical service, and for the ambitious student untold opportunities for acquiring scientific and practical attainments.

A year ago the State Board of Charities sent a circular letter embodying the above views to the trustees of the four State lunatic asylums, and requested also a conference of the superintendents and the President of the State Board. At this meeting, the subject was thoroughly discussed and the result was the appointment of a board of examiners to conduct a competitive examination on a truly impartial basis. This board consisted of the following gentlemen, who were to prepare questions in their respective branches:

Dr. R. Dewey—Mental Diseases.

Dr. J. H. Etheridge—Gynecology.

Dr. Adolph Meyer—Anatomy and Physiology of the Nervous System.

Dr. Louis McArthur—Surgery.

Dr. Hugh Patrick—Nervous Diseases.

Dr. William E. Quine—Medicine.

This board appointed at its first meeting,

Dr. Boerne Bettman—President.

Dr. Hugh Patrick—Secretary.

The board prepared the following circular letter, a copy of which was sent to every medical college in the State in good standing with the State Board of Health:

CHICAGO, April 5, 1895.

Notice is hereby given that a competitive examination will be held at Cook County Hospital, April 15, 1895, from 9 to 4 o'clock, for the appointment of internes to serve for a term of one year in the State Hospitals of the Insane, to be appointed as follows:

Northern Illinois Hospital for Insane, three internes (Elgin).

Eastern Illinois Hospital for Insane, four internes (Kankakee).

Central Illinois Hospital for Insane, three internes (Jacksonville).

Southern Hospital for Insane, two internes (Anna).

All senior students of, and all practitioners graduated within five years, from medical colleges recognized by the Illinois State Board of Health shall be eligible for this examination.

Candidates shall be examined in the following branches, viz.: practice of medicine, surgery, gynecology, mental diseases, nervous diseases, anatomy and physiology of the nervous system.

Each interne before entering upon his duties shall have complied with the legal requirements governing the practice of medicine in the State of Illinois.

Beside board and lodging, internes shall receive a monetary compensation not to exceed \$20 per month.

Applicants will oblige the Board by immediately sending their names to Dr. Hugh T. Patrick, 34 Washington Street, Chicago.

By order of the Board of Examiners.

BOERNE BETTMAN, M.D., President,

HUGH T. PATRICK, M.D., Secretary.

Owing to unfortunate obstacles placed in the way of the Examining Board, the above announcement was not made until a late date, less than a week before the date of examination. Notwithstanding the short preparatory notice, nineteen applicants reported to the Secretary. Seven of these withdrew at the last moment, partly on account of a rumor which crept into the newspapers that internes were to be utilized as nurses. Six of the twelve aspirants obtained an average of 75 per cent. or more. One of these succeeded in obtaining a position in the Cook County Hospital. The remaining five drew lots, which resulted in two being assigned to Kankakee, one to Elgin, one to Jacksonville and one to Anna.

The seventh and eighth highest in rank having obtained an average of 70 per cent. were appointed first and second alternates. The examination was absolutely fair; the identity of the applicants was lost, by withholding from their papers, names and any sign or symbol which might disclose them. A card bearing the name and given number of each candidate was placed in a sealed envelope, which was only opened after the papers were examined and the winning number had been decided upon. This examination marks an epoch in the history of State medicine. Although the City of Chicago has but recently adopted at the polls, by an overwhelming majority, civil service reform, to the medical fraternity belongs the credit of having first conceived the plan and carried it into execution. The fundamental principle of all good government should be, "to the worthy belong the deserts," in contra-distinction to the war cry of political parties, "to the victor belongs the spoils."

As our superintendents are medical men, they

naturally will do all in their power to protect from harm the seed which has been planted, so it may sprout and develop into a sturdy plant, which will bear rich and bountiful fruit.

## SOCIETY PROCEEDINGS.

### Association of American Medical Colleges.

*Sixth Annual Meeting, held at the Club House of the Hotel Rennert, Baltimore.*

DR. E. FLETCHER INGALS, President, in the chair.

The minutes of the last meeting were read and approved, upon amendment, changing the records to indicate the presence of the representatives of the University of California and the Western Pennsylvania Medical College of Pittsburgh, Pa.

DR. MICHAEL raised a point denying the legality or regularity of any action taken at San Francisco at the last meeting, as only twenty-three colleges were represented out of a total enrollment of forty-one colleges. The point was discussed by Drs. Millard, Cole, Street, King, White, Roberts, Thomas and Graham. The chair ruled this point as not well taken and that a legal meeting was held.

Roll call indicated the following named colleges represented by delegate, and were reported to the Secretary as being the official list of the present membership as called for under the amended Constitution and By-Laws. [To be published later.]

The Secretary submitted his annual report, which was adopted.

DR. N. S. DAVIS presided during the reading of the President's Address. [To be published later.]

Upon motion of DR. COLE, the address was adopted and ordered printed and also ordered circulated to all teachers of medicine in the country.

Upon motion of Dr. Millard, the President appointed a committee consisting of Drs. Osler, Baker and Graham to submit the names of distinguished teachers for honorary membership. The committee reported the following named persons: H. P. Bowditch, Harvard; Geo. H. Sternberg, Surg.-Gen. U. S. Army; J. M. DaCosta, University of Pennsylvania; N. S. Davis, Chicago Medical College; Levi Cooper Lane, Cooper Medical; Hunter McGuire, University Medical College; T. Gaillard Thomas, Columbia College. The report was adopted and the names reported elected to honorary membership.

The Secretary submitted the report of the committee on syllabus, and minimum of requirements, and upon request of the committee the sub-committee, consisting of Drs. Millard, H. A. Kelly and Bayard Holmes, were directed to make the necessary amendments and to print the same in the proceedings of the fiscal year.

The Constitution was by a unanimous vote amended, to provide that the annual meetings begin Monday, A.M., of the week in which is held the meeting of the AMERICAN MEDICAL ASSOCIATION.

DR. HOLMES presented a paper upon Libraries for Medical Schools, which was read and ordered printed.

The following notice of amendment to the Constitution was previously submitted by the Dean of the College of Physicians and Surgeons of Baltimore, to-wit: that Sec. 4, of Art. III of the Constitution be amended to read as follows: "Candidates for the degree of Doctor of Medicine in 1904 and thereafter, shall have pursued the study of medicine for a period of four years, and attended at least four courses of lectures of not less than six months' duration each," was read and discussed by Drs. Michaels, Holmes, Millard, Cramer of Omaha, Friedenwald, Culbertson, Davis and Cole. Upon vote, the amendment was defeated by a vote of 30 nays to 5 ayes.

Upon motion, the action taken at California relating to the curriculum of study was confirmed.

The Judicial Council through its Chairman, Dr. Dudley S. Reynolds, reported as follows: in the matter of complaints against the College of Physicians and Surgeons of St. Louis the Council reported the methods, as disclosed, in bad taste and not in accord with the rules of the College Association. In the matter of the reference of the Ft. Wayne Medical College, regarding the matriculation of students, the action of the school was sustained.

In the matter of the communication of Dr. J. A. Larrabee of the Hospital Medical College, relating to the action of

the Association in expelling the Kentucky School of Medicine from membership in this body, the Council reported that it had no opinion to express.

In the matter of the communication of Thos. H. Hoover, Regent of the Starling Medical College, the Council reported lack of definite information.

The rules submitted by the Judicial Council were adopted.

Upon motion of Dr. Larrabee, the colleges connected with the Southern Association of Medical Colleges were invited to make application for membership in this body.

In the matter of the application of the College of Physicians and Surgeons of Boston, and the Woman's Medical College of the Presbyterian Church of Cincinnati, the question of admission to membership was referred to the Judicial Council with power to act.

DR. J. A. LARRABEE moved that the disability of the Kentucky School of Medicine be removed, and it be permitted to apply for membership. The motion was seconded by the Secretary and adopted.

In response to a unanimous expression of the Association, the following named colleges were elected to renewed membership: the University of Louisville, the Louisville Medical College, the Kentucky School of Medicine.

The following officers were elected for the ensuing year: President, Wm. Osler; First Vice-President, J. M. Bodine; Second Vice-President, W. Graham; Secretary and Treasurer, Bayard Holmes. Judicial Council, Reynolds, Pancoast and Vaughan.

DR. COLE of the University of Colorado, submitted the following notice of proposed amendment to the Constitution and By-Laws, to wit: that Sec. 4, Art. III, be amended to read: "That the preliminary examination provided for, shall be conducted by a Board of Examiners in no wise connected with a teaching body of a medical college."

Upon motion, adjourned.

PERRY H. MILLARD, Secretary.

### PRELIMINARY REPORT OF THE COMMITTEE OF THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES ON SYLLABUS OF A FOUR YEARS' COURSE OF MEDICAL INSTRUCTION.

In presenting this preliminary report your committee appointed at Baltimore, May 5, finds itself facing a problem requiring much time and study, and an emergency in the evolution of medical education calling for great promptness. Many schools are passing from a three year, and largely ungraded course, to a four year graded course. The traditions of the past must be violated and no authority or precedent for the new order is at hand.

Your committee wishes, therefore, to place before the colleges all the information in its possession, taking a very broad and liberal view of its duties. The reports of the sub-committees are given almost always in full. In a few cases it has been necessary to cut them down. The committee is unable to coördinate and simplify the syllabi, and recommend a complete syllabus of the full course at this time. It is possible that such a syllabus might be looked upon as interfering in a measure with the freedom of the teachers, even though it would be advisory only.

It is far from the intention of the Association to interfere in any way with the complete liberty of schools or teachers in the presentation of medical teaching, or crystallize upon them a course of study which would prevent or delay further progress.

So many teachers and so many colleges are calling for help in re-organizing their courses of study, that this incomplete report is offered with the hope that at the next annual meeting of the Association a complete and final syllabus may be handed in. Criticism and correspondence is solicited.

Before making a syllabus of the minimum required course of study for the guidance of members of this Association, it seems necessary to establish some unit of measure. The most common unit now in use among educators is, perhaps, the sixty recitation hour unit; or a recitation of one hour each day, five days in the week for twelve weeks, that is for three months. This unit of sixty recitation hours will be used in this report.

The following questions naturally present themselves and the discussion shows the present opinions of the committee:

1. How much work should be required of the student each year?

The student can reasonably be expected to work ten hours a day. Every recitation or lecture hour should require one and one-half hours of preparation. Four recitation hours would make the student's working day ten hours long. In medical schools the students are old enough and mature enough to stand this amount of work. Four recitation hours

would be equal to  $9\frac{1}{2}$  units of 60 recitations each for the minimum year of seven months. The four years would give a total of  $37\frac{1}{2}$  such units.

#### 2. How can laboratory work and clinics be measured?

Much of the work in the medical colleges is either laboratory or clinical work. Neither of these requires much time for preparation, outside the time consumed in the laboratory or clinical amphitheater. Laboratory or clinical work may be reasonably counted as half time. Two laboratory hours or two clinic hours equal one recitation hour.

#### 3. What should be the proportion of lectures or recitations, of laboratory work and of clinical work?

The committee is of opinion that the proportion of lectures or recitations is now in most American institutions much too large. For the present, we recommend that the work of the four years be nearly equally divided into three portions: one-third being given by means of lectures and recitations, one-third by laboratory methods and one-third as clinical teaching.

#### 4. Shall all of this minimum of $37\frac{1}{2}$ units be required, or may some of it be elective?

We believe that the larger portion of this minimum should be definitely laid out and required of every student by his college, but we urge that each college have a group of courses measured the same as other work which students may elect to fill out the full complement of courses required.

#### 5. Is any particular order in the curriculum necessary or desirable?

Certain branches are necessarily primary, others are necessarily final. Anatomy is, for example, a primary study, and with physiology, embryology and bacteriology it should come before pathology. Pathology should be followed by general medicine and surgery, and these by the specialties. While no definite order is necessary, a certain natural sequence should be observed, so that the student may be led from the known to the unknown, from the concrete to the abstract, and from the special to the general. In this connection the sub-committees present many valuable ideas and suggestions.

Signed, HOWARD KELLY,  
BAYARD HOLMES.

DR. N. S. DAVIS JR., gave a report on

#### MINIMUM OF REQUIREMENTS.

*First Year.—Lectures and Recitations—Hours per week.*—Anatomy four, physiology four, histology and embryology two, chemistry three; *laboratory exercises*, physiology two exercises a week, chemistry three exercises a week, histology and embryology three exercises a week, bacteriology three exercises a week. Dissections. [120 hours].

[In a nine months course this would equal about 15 units].

*Second Year.*—Anatomy two, surgical anatomy and operations two lectures and recitations, practical exercises [60 hours], general pathology three lectures and recitations, pathologic laboratory three exercises, physiologic laboratory three exercises, physical diagnosis two lectures and recitations, materia medica two lectures and recitations. Dissections [120 hours].

[In a nine months course this would equal about 11 units].

*Third Year.*—Practice two lectures and recitations, surgery two lectures, obstetrics three lectures, therapeutics three lectures, hygiene one lecture, pedology one lecture, dermatology one lecture.

Clinical instruction: medicine three hours, surgery three hours, gynecology one hour, eye and ear one hour, pedology two hours, dermatology two hours, mental and nervous one hour.

[In a nine months' course this would equal about 10 units.]

*Fourth Year.*—Practice two lectures and recitations, surgery two lectures, orthopedia one lecture, gynecology two lectures, mental and nervous one lecture, eye and ear one lecture, jurisprudence one lecture and recitation half year, laryngology one lecture and recitation half year.

Clinical instruction: medicine three hours, surgery three hours, gynecology one hour, eye and ear one hour, pedology two hours, dermatology one hour, mental and nervous one hour, orthopedics one hour, laryngology one hour.

[In a nine months course this would equal about  $10\frac{1}{2}$  units.]

By laboratory exercises, is meant exercises not to exceed two hours in length. The arrangement by years is capable of deviation. The time allotted to some of the topics may with advantage be increased. The clinical exercises may likewise be extended to advantage. Each student should be furnished an instrument or microscope for laboratory use. In the chemic laboratory each student should have his own

desk and apparatus. Ample equipment of all laboratories should be insisted upon.

#### SCHEDULE OF MINIMUM OF REQUIREMENTS.

This represents the minimum amount of work in each branch entitling colleges to remain in active membership in this Association. See report of 1894.

Represented in hours "D," indicates lectures or recitation exercises. "L," indicates laboratory work.

Histology and embryology, D, 50, L, 700; anatomy, D, 100, freshmen; D, 100, juniors; laboratory, 100; dissection of entire body.

Physiology, D, 100, L, 75; chemistry, D, 125, L, 125; bacteriology, D, 25, L, 150; hygiene, D, 25; medical jurisprudence, D, 12; practice, D, 200, weekly clinical instruction; surgery, D, 200, weekly clinical instruction; surgical anatomy, D, 100, including laboratory work; obstetrics, D, 150, including recitations; ophthalmology and otology, D, 25; mental and nervous, D, 25; materia medica and therapeutics, D, 125; dermatology, D, 25; orthopedia, D, 25; genito-urinary, D, 25; pedology, D, 25; physical diagnosis, D, 75; pathology, D, 50, L, 100; laryngology, D, 25.

DR. BAYARD HOLMES, of Chicago, presented a report on

#### AN IDEAL WORKING FOUR-YEAR MEDICAL COURSE, LEADING TO THE DEGREES A. B. AND M.D.

Prepared for a university having regular and homeopathic medical teaching. A major equals one of the 60 hour units used above.

Admission to this course is granted only to those who have completed the sophomore year at this [any] university and to those who pass an examination on the required work, as laid down in the university calendar.

The University College embraces thirty courses of sixty recitation hours each. This college requires two years of work. When these thirty courses are completed, the student will receive A. B. at the succeeding Commencement. The required courses of the University College are as follows:

- (a). Chemistry, organic, toxicology, 2 majors.
- (b). Medical botany and pharmacognosy, 1 major.
- (c). Pharmacy, 1 major.
- (d). Biology, I, Huxley and Martin, elementary biology. Martin and Mole, I, II, III, 3 majors—2, bacteriology, 1 major.
- (e). Histology of a mammal, histologic technique, 3 majors.
- (f). Embryology, 2 majors.
- (g). German, 2 majors.
- (h). Medical bibliography and methods of research,  $\frac{1}{2}$  major.

(i). Experimental or laboratory physiology, including experimental psychology, 6 majors.

(j). Human anatomy, 4 majors—dissections, 1 major.

Students who already have any part of this course may elect under the direction of the Dean, such accessory branches as are necessary to complete the required amount of work.

The Professional College embraces thirty majors in medicine, with a wide margin of electives. This college requires two years work. The required courses are the following:

- (a). Pathology, 3 majors.
- (b). Medicine, 3 majors.
- (c). Surgery, 3 majors.
- (d). Obstetrics, 2 majors.
- (e). Elementary State Medicine, 2 majors.
- (f). Elective in specialties, 6 majors.

The eleven electives must be taken with the advice and consent of the Dean, and they must be properly proportioned among clinics, lectures, researches, and theses offered every year. The elective work should be laid out as occasion requires. The following is only suggestive:

Ophthalmology, 1 major.

" second, 1 major.

Otology, 1 major.

" second, 1 major.

Laryngology, 1 major.

" second, 1 major.

Male genito-urinary surgery, 1 major.

Homeopathic materia medica, 1 major.

" therapeutics, 1 major.

" practice of medicine, 2 majors.

Dental surgery, 2 majors.

" 3 majors.

Gynecology, 1 major.

" second, 2 majors.

Orthopedic surgery, 1 major.

" second, 1 major.

Medical jurisprudence, 1 major.

Study and research in medical laws of the United States, (thesis work), 1 major.

Vital statistics, 1 major.

Elements in the fluctuation of vital statistic research, (thesis work), 1 major.

Laws relating to hospitals in the United States, research, (thesis work), 1 major.

State Boards of Health, study of results, origin, laws and evolution research, (thesis work) 1 major.

The development of the child to manhood. The normal child. The abnormal factory child, research, (thesis work), 1 major.

Blindness, history, etiology, education of blind in United States, expense, possible reduction of expense, methods. (Thesis work), 1 major.

The defectives of the United States. Origin, cost and possible limitation. (Thesis work), 1 major.

The Health Officer, his duty and privileges. (Lectures), 1 major.

Life insurance examinations. The duties of the physician and the company, 1 major.

The railway and corporation surgeon. His duties, privileges and his emergencies. (Lectures), 1 major.

Child labor. Lectures and class research. Semmarium, 1 major.

These courses may be multiplied, as the resources of the institution increase. The same degree should be given to all medical students, on the same amount of work.

The seminar and theses courses require much original work and are conducted by a teacher with a small class. Two hours, one meeting a week equals five recitation hours, and a major is therefore completed at the end of three months.

The following circular was sent out to guide the sub-committees in their work.

#### THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

##### *Circular of Information to Sub-committees on Syllabus of Studies.*

*Gentlemen:*—At a regular annual meeting of the Association of American Medical Colleges held in San Francisco, Cal., in June, 1894, the Constitution of the Association was changed, providing that hereafter candidates for the degree of M.D. be required to have completed attendance upon at least four courses of lectures before receiving a degree. Beginning with this year, the course of study is therefore extended to four years, with attendance upon at least four courses of lectures, of not less than six months duration, in different years.

The action of the Association upon this most important move was substantially unanimous.

There was likewise appointed at this session, a General Committee on "Minimum of Requirements" and "Syllabus of Lectures." The committee consists of the following named persons, to-wit: Professors P. S. Conner, of Cincinnati, Ohio; C. B. Stemen, of Fort Wayne, Ind.; Victor C. Vaughan, of Ann Arbor, Mich.; Wm. E. Quine, N. S. Davis Jr., and E. Fletcher Ingals, of Chicago, Ill., and Perry H. Millard, of St. Paul, Minn.

It is the purpose of this committee to aid in bringing about greater uniformity in the methods of admission of students to the study of medicine, in the admission of students to advanced standing with credits from other colleges, in the classification of students and in methods of instruction.

The General Committee held its first meeting in Chicago, Nov. 30, 1894. It was deemed advisable to act with deliberation and seek the advice and coöperation of some of the leading educators of the country in the preparation of a syllabus, and to divide the work of its preparation into a number of sub-committees, corresponding in number to the number of different chairs to be represented in the proposed four years' course.

By resolution of the General Committee, the different chairmen are at liberty to enlarge the number of their committee, or to perform their work without assistance. The following named persons were selected to serve as Chairmen of the different sub-committees, to-wit:

History and Embryology, T. Mitchell Pruden, New York.

Anatomy, Thomas Dwight, Boston.

Physiology, Henry P. Bowditch, Boston.

Chemistry, Walter S. Haines, Chicago.

Bacteriology, Roswell Park, Buffalo.

Hygiene, Victor C. Vaughan, Ann Arbor.

Medical Jurisprudence, B. S. Folsom, Boston.

Materia Medica and Therapeutics, H. C. Wood, Philadelphia.

Practice, Wm. Osler, Baltimore.

Gynecology, Howard A. Kelly, Baltimore.

Surgery, P. S. Conner, Cincinnati.

Obstetrics, W. W. Jaggard, Chicago.

Pathology, Wm. Welch, Baltimore.

Mental and Nervous, Daniel R. Brower, Chicago.

Diagnosis of the Chest and Physical Diagnosis, E. Fletcher Ingals, Chicago.

Ophthalmology, E. L. Holmes, Chicago.

Otology, Henry Gradle, Chicago.

Pædology, T. M. Rotch, Boston.

Genito-Urinary, J. H. Dunn, Minneapolis.

Orthopedia, Virgil C. Gibney, New York.

Laryngology, James N. Mackenzie, Baltimore.

History of Medicine, N. S. Davis, Chicago.

The sub-committees are requested to report, covering the following points in particular:

1. In a four years' course of not less than eight months' duration each year, how much time do you suggest be devoted to your branch?

2. Of the whole number of hours recommended, how divide as to didactic, laboratory, recitation and clinical instruction?

3. At what time in a four years' course should the instruction in your branch be afforded?

4. Any suggestions of subjects to precede your branch before permitting the student to enter upon the same?

5. Is it wise to credit work done in other schools, or would you recommend that students be admitted to advanced standing, only after an individual examination in each branch, below the class the student may desire to enter?

6. Suggest a rule for the classification and grading of students suitable to a four years' graded course of instruction.

7. Prepare a detailed syllabus of the topics you deem suitable for instruction in your branch, and their manner of presentation to the student.

It is intended to combine the report of the several committees and issue the same as "A Syllabus for the Use of Teachers and Students of Medicine."

The members of the different committees are requested to submit their reports to the Secretary at St. Paul, Minn., not later than March 1, 1895. A joint meeting of the General and sub-committees will occur before the meeting of the Association, which took place in Baltimore in May of the present year. Respectfully submitted,

PERRY H. MILLARD, M.D.,

Secretary Association American Medical Colleges.

#### REPORT OF SUB-COMMITTEE ON MATERIA MEDICA.

In a four years' course of not less than eight months' duration each year, materia medica and therapeutics should receive attention during three of these years, viz., the second, third and fourth years. Instruction should be given as a graded course.

*First Year. Introductory Work. Botany.*—By beginning the study of materia medica the second year in the course, the student has an opportunity to receive instruction in botany and chemistry during the first year. Botanical knowledge should be insisted upon, and the necessary instruction for the acquirement of such knowledge should consist of at least thirty hours devoted to lectures or recitations with some additional time for laboratory work.

*Second Year. Materia Medica.*—During the second year, two hours weekly should be devoted to the study of materia medica, giving special attention to pharmacognosy and pharmacology. Such instruction should by preference be given in the laboratory and supplemented by recitations.

*Third Year. Therapeutics.*—Two hours weekly for the school year, should be given to therapeutics studied from the drug standpoint. Such instruction may be given by lectures. In this work, drugs may be studied individually, as represented by such writers as Waring and Ringer, or collectively as represented by the works of H. C. Wood, Bartholow, etc.

*Fourth Year. Therapeutics.*—Two hours weekly, for the school year, should be given to the subject of therapeutics studied from the standpoint of disease. Such instruction should be given by didactic and clinical lectures. The character of such work is well represented by Hare's "System of Practical Therapeutics." H. M. BRACKEN, M.D.,

Professor Materia Medica and Therapeutics,  
University of Minnesota.

#### REPORT OF SUB-COMMITTEE ON ANATOMY.

[In conformity with your request of April 19, I make the inclosed suggestions regarding the character and order of

work to be done in anatomy, in a four years' course. This, as you note, does not include any work in histology and embryology. These studies should in most part be synchronous with the lectures in anatomy. The histology coming in the first year and the embryology in the second year. This course, as outlined, is practically what is being done in the college at the present time.—G. A. HENDRICKS.]

The greater portion of the student's work in anatomy is memorizing names and the forms of objects. Lectures do not give him much assistance. The individual must do this himself. He can, however, be materially aided in his work by pursuing it logically under the guidance of an instructor, by the use of the objects to be studied, and by the stimulation of frequent recitations.

Technical terms should be learned, as far as possible, in the first year. The feature of this year's work should be the study of specimens in the laboratory, supplemented by frequent recitations from the object. Lectures are of minor importance, and should be confined more to generalizations than to minute descriptions.

The dissection and study of muscles may be done in the first year, after the study of bones and joints, and following the lectures and demonstrations on myology.

The work of the second year should be so arranged that the description of the viscera should precede the advanced course in histology and embryology, and the lectures on the physiology of these organs.

Dissecting should be done in the second year, and should not begin until the lectures are so far advanced that the student follows the class-room demonstrations. In point, the student should not dissect to understand the lectures, but the lectures should explain and direct him in his practical work.

The instruction of the third year, unless it can be given in the laboratory, must be done by lectures.

#### *Course of Study First Year.*

**Introduction:** Principles of systematic zoölogy. Fundamental characteristics of vertebrates. Classifications of skeletons. Bones—classification. Bones—features, classification of. Typical vertebra, ten hours.

**Etiology:** Lectures and recitations, thirty hours. Laboratory work—sections, each section twenty-one afternoons, each week six hours, eight weeks forty-eight hours. One lecture per week. Two recitations per week.

**Syndismology:** Lectures and recitations twelve hours.

**Myology:** Lectures and recitations thirty hours.

**Laboratory work.** Two afternoons each week, six weeks, thirty-six hours. Two lectures per week. One recitation per week.

Attendance upon second year lectures covering thoracic, abdominal and pelvic viscera.

#### *Second Year.*

**Organs of circulation, respiration, digestion, reproduction, genito-urinary, thirty hours.**

**Abdominal walls, regions, contents.**

**Hernia—inguinal, femoral, perineum.**

**Anatomy of scalp, face, neck. Anatomy of thorax, axilla, arm, forearm, etc. Anatomy of pelvis, thigh, leg, thirty hours.**

**Nervous system, cord, brain and membranes. Cranial nerves, spinal nerves. Sympathetic system, twelve hours.**

#### *Third Year.*

**Regional or surgical anatomy: Landmarks; surface markings. Review of descriptive anatomy by recitation. Surgical regions, demonstration of relations. Location and position of viscera. Advanced anatomy of brain and cord. Advanced anatomy of special sense organs.**

BOSTON, MASS., March 19, 1895.

DR. P. H. MILLARD, *Dear Sir:*—I feel that I owe you an apology for never having answered your letter of two or three months ago. I consulted one of my colleagues as to what course to take. He gave me no opinion, and I forgot all about it. It is out of the question for me to give you, now, an elaborate or formal answer or to call a committee together; but owing to my previous neglect I can not do less than give you my personal and informal opinion.

The question, if I remember right, was as to what is the best arrangement of a course in anatomy in a four years' course?

This must vary with the school. The course here includes two years. In the first, is taught histology, embryology and descriptive anatomy. This, however, is taught more and more topographically from the very beginning.

In the second year, there is advanced anatomy and ap-

plied anatomy. Though it does not do so with us, this should include all surgical and surface anatomy.

Dissecting should certainly be carried on through a part of both years. It is not well to have it begin before the student knows the bones and joints. On the other hand, it should not be finished in the first year, as the student will appreciate it more in the second. Regretting that I can not give you a formal report, I am

Yours very truly,

THOMAS DWIGHT.

Harvard University Medical School.

#### REPORT OF THE SUB-COMMITTEE ON CHEMISTRY.

For various reasons it does not appear advisable, at least for the present, to prescribe any rigid and definite rules for the course of instruction in chemistry in medical colleges. The science is one of such great breadth, and opinions among the best men in the department vary so widely as to exactly what subjects should be selected for study, and as to the best means of imparting instruction regarding them, that it seems better to allow a wide latitude for the individual choice of each teacher, prescribing only in a general way the work that should be required in colleges belonging to this Association. Your sub-committee, therefore, presents below its views regarding the minimum requirements of instruction in chemistry in medical colleges. No institution should give less than this, and it is to be hoped that all will give more. The subjects for instruction and the arrangement of the different courses are given only in brief outline, the details of the course being left to the judgment of the individual teacher.

One of the requirements for admission to the colleges belonging to this Association is a fair knowledge of the elements of physics, and this requirement should be insisted on most strenuously. There is not a department of medicine that does not need this knowledge for its intelligent study. This is especially true of chemistry, and with many colleges it is customary to precede the instruction in this branch by a short course in physics. This seems undesirable, as it takes valuable time from the study of chemistry, and, moreover, it is unnecessary if the requirements for admission are adhered to—physics having already been studied before entrance to the college is granted. If deemed advisable, a separate course of instruction in somewhat advanced physics might advantageously be given during the first year; but it would seem best to have this totally independent of the course in chemistry, so that the time assigned to the latter may not be at all abridged.

The study of chemistry, therefore, should begin with the commencement of the first year's course, and it should be continued during, at least, the first and second of the required four years in the medical college. The first year may be profitably devoted to inorganic chemistry, with perhaps an introduction to organic chemistry. The instruction should consist of lectures, recitations, and laboratory work. To the first and second not less than seventy-five hours should be given, and fully one-half of this time should be devoted to recitations. At least twenty-five laboratory exercises, of not less than two hours each, should be given to every student during this year.

In the second year, organic chemistry may be taken up, or if already begun in the first year, may be continued, and, following this, a course should be given in physiologic chemistry, when especial attention should be devoted to the urine, both in health and disease. During this year, also, instruction may advantageously be given in toxicology, unless that subject is taken up in connection with the different poisons as they are treated in the general course. At least seventy-five hours should be assigned during this year to the didactic consideration of these subjects, and not less than one-half of this time should be given to recitations. Fully twenty-five exercises of not less than two hours each should be devoted to laboratory work.

At fixed intervals during the entire course, written examinations may advantageously be given to test the progress of the class, and final examinations should be given at the end of each of the two years on the subjects taught therein.

The sub-committee would suggest that the subjects to which the most time is given, in both years, be those most intimately connected with medicine. Those elements and compounds should be particularly studied which are of use in the healing art, while those not employed in medicine, or of purely theoretical importance should be either omitted or very briefly discussed. Thus, iodine, mercury, alcohol and strychnin should be dwelt upon at length, while cobalt, zirconium, hexane, and the azo colors may be dismissed with a few words, if mentioned at all. The field of chemistry is so

exceedingly broad that unless some limitation of this kind is practiced, many subjects of the deepest interest in medicine must necessarily be omitted.

While, as before stated, practically all the work in chemistry may be completed in the first two years of the four years' course, yet it would seem highly advantageous to introduce a small amount of instruction in what might be called clinical chemistry into the last year. One exercise a week might be given to the work, chiefly perhaps in the laboratory, when the examination of urine, gastric juice, and other secretions, tests for the more important elements and compounds, and the incompatibility of drugs in prescriptions could be reviewed. This would afford an excellent means of reviving a knowledge of the more important parts of medical chemistry, and the practical value of this department would then be more fully appreciated than before, since the student, having acquired a greater knowledge of disease, would be in a position to appreciate the relation of chemistry to morbid processes, their recognition and their treatment.

Your sub-committee would suggest that students coming from other colleges, belonging to this Association, receive credit for work already done in the other institution, upon presentation of a certificate from the professor of chemistry, or from the dean or secretary of the other college. It would also seem desirable that students who have taken at least two years of didactic and practical chemistry in high grade literary and scientific schools, and graduates of colleges of dentistry and pharmacy should be admitted without examination to the second year of chemistry in the medical college, upon presenting a proper certificate of work from the other institution.

In conclusion, your sub-committee would state its entire agreement with the views presented by Professor Huxley a number of years ago, that the study of general chemistry has no proper place in the curriculum of a medical college; that this should precede the study of medicine, and that medical chemistry alone should be taught in medical schools. It is certainly to be hoped that this opinion may be adopted by this Association, and that, before many years have passed by, a good knowledge of general chemistry will be required for admission to Association colleges. Instruction in chemistry in the medical college, then, could be confined to its legitimate field—medical chemistry; and, with an abundance of time for its study, the subject would quickly assume its rightful place as one of the most interesting, important, and profitable parts of medical learning.

Respectfully submitted,

WALTER S. HAINES, M.D., Rush Medical College.

(To be continued.)

### Kentucky State Medical Society.

*Abstract of the Proceedings of the Fortieth Annual Meeting, held at Harrodsburg, June 12, 13 and 14, 1895.*

#### FIRST DAY—AFTERNOON SESSION.

The Society convened in the court-house and was called to order by the President, Dr. J. B. MARVIN, of Louisville.

Prayer was offered by the Rev. Dr. W. O. GOODLEE.

An eloquent Address of Welcome was delivered by the Hon. BEN. LEE HARDIN.

The Committee of Arrangements then made its report.

The reports of the Permanent Secretary and Treasurer were next read and adopted.

There being no further routine business to be disposed of at this time, the reading of papers was proceeded with.

Dr. WILLIAM BAILEY, of Louisville, read a paper entitled "Sanitation in Connection with Diphtheria," in which he said that in order to intelligently discuss diphtheria we must first take sanitation into consideration. Great credit was due to the work that had been done by bacteriologists. He had no new theory to advance as to the cause of the disease. It is a specific disease, due to a specific cause, which is always present when the disease exists. The consensus of opinion among those prepared to judge was that the Klebs-Löffler bacillus was the specific germ responsible for the production of the disease; hence the work to do in diphtheria was to destroy the germ or to restrict its activity. The isolation of cases should be as complete as in cases of smallpox. The room selected for the sick should, by preference, be at the top of the house and completely cut off from other parts of the house. The room should be denuded of hangings and belongings in order to facilitate the necessary disinfection afterward. Dr. Bailey then briefly referred to the antitoxin treatment in the prevention of diphtheria.

Dr. CARL WEIDNER, of Louisville, read a paper on "Pathology and Bacteriology of Diphtheria." A disease which corresponds to the clinical picture of to-day seems to have existed as far back as we can trace medical history. The disease appeared in the New England States in the eighteenth century. Diphtheria was a specific disease *sui generis*. Our literature in regard to it is becoming more voluminous from year to year; and clinical investigations are following one another in rapid succession. The work of several eminent investigators was mentioned along this line. The author emphasized the importance of knowing the cause of things, and quoted the words of an eminent practitioner: "First to know, then to heal." He next dwelt upon the different micrococci, but more particularly the Klebs-Löffler bacillus. The investigations made from 1887 to 1889 demonstrated conclusively that the true and only cause of diphtheria was the Klebs-Löffler bacillus. Many investigators have since reported cases of suspected diphtheria in which the bacillus found corresponded in every way with that described by Löffler; but all cases in which the bacillus of Löffler is not found are now considered pseudo-diphtheria. From a prognostic standpoint it is important to make a distinction between diphtheria produced by the bacillus of Löffler and pseudo-diphtheria.

Dr. W. McCURE, of Lexington, followed with a paper on

#### CLINICAL DIAGNOSIS AND LOCAL TREATMENT OF DIPHTHERIA.

The author showed that mere clinical diagnosis is extremely unreliable and should never be relied upon where more accurate diagnostic means are at hand. In support of this statement, he cited the fact that in 1893 the New York City Board of Health instituted a series of bacteriologic examinations, and, according to their report, examined 5,611 cases that had been clinically diagnosed diphtheria. Of this number the Klebs-Löffler bacillus was found in 3,255 cases, while in the remaining 1,540 cases no Klebs-Löffler bacilli were found. It will thus be seen that the number of mistaken diagnoses amounted to 32 per cent. The author in his argument proceeded with the assumption, which he thinks has been clearly proved, that there is no true case of diphtheria without the presence of the Klebs-Löffler bacillus, which he regards as the specific agent. In most cases there is a prodromal stage lasting a few days, resembling a catarrhal pharyngitis. There is a slight fever together with painful deglutition, more marked when swallowing liquids than solids, headache and occasional vomiting.

Of the numerous remedies used locally in the treatment of the disease, the ones that are most generally resorted to and have given the greatest satisfaction are chlorate of potassium, nitrate of silver, chromic acid, iodine, corrosive sublimate, methyl blue, tincture of iron, carbolic acid, and peroxid of hydrogen. The tincture of iron is mostly beneficial on account of the free hydrochloric acid it contains. The nitrate of silver is but a superficial caustic, while chromic acid is too heroic in its caustic effects. In peroxid of hydrogen we have a valuable adjunct in the treatment of diphtheria, when judiciously and skillfully used. It is a valuable aid in diagnosis, as by its application to the throat, if there be but a small trace of membrane, it causes it to assume a white color and on this a fine foam to rise, caused by the liberation of oxygen gas.

Dr. THOMAS HUNT STUCKY, of Louisville, presented a paper on "Sequelæ and General Treatment of Diphtheria." The most important sequelæ are paralyses, which may follow mild as well as severe cases. Paralysis occurs in from 15 to 20 per cent. of the usual run of cases. In the more malignant cases paralysis occurs in about 40 per cent. The palate is most usually affected. The organ of special sense most affected is the eye. Speech, like other senses, is not involved. Brachycardia and tachycardia may be observed in the same patient. The Klebs-Löffler bacillus and streptococci have a tendency to produce exudates and pseudo-membranes. The latter are examples of mixed infection. Dr. Stucky then referred to the rapid strides that have been made by the introduction of antitoxins in the prevention of diphtheria. The most noteworthy point about the antitoxin treatment is that we know nothing about its definite composition, and no one has undertaken to give us an analysis. Supportive treatment was next referred to. The treatment may be summed up thus: 1, prophylaxis; 2, hygiene of the sick room; 3, local applications. Local treatment is of little value as a curative measure. When the lesion is once established gargles are useless. The treatment of special symptoms, such as paralysis, call for strychnia or other tonics; massage, or the electric current may be used; also the hypodermic injection of antitoxins; if there is cardiac

weakness, absolute quiet in the recumbent position should be enjoined. The hot pack is especially serviceable when dyspnea or marked nervousness is present. Stimulants and cardiac tonics should be given early in the disease and constantly. Strophanthus, digitalis, strychnia, camphor and alcohol are the remedies most in favor. Citrate of caffeine may be given when the urine is scanty for its diuretic, as well as cardiac effect.

Dr. WILLIAM CHEATHAM, of Louisville, read a paper on "The Serum Treatment of Diphtheria." The author is much in favor of the serum treatment of the disease. The method of administering it was too well known to the members for him to repeat it at this time. Practitioners, however, must practice thorough cleanliness of the parts in connection with its use. The needles should be clean. The author carries his needles in absolute alcohol. Cleanliness of the parts affected must also be carried out. The tearing away of diphtheritic membrane or any kind of rough treatment should be dispensed with and the spray and gargle substituted. The serum treatment of diphtheria is as yet in its infancy, the dose of it not being well understood. Dr. Cheatham said the best report on the antitoxin treatment of diphtheria was that made by Dr. Kinyoun, of Washington, D. C., under the auspices of the United States Marine-Hospital Service. Future possibilities in this direction could not be over-estimated, as we have in it a preventive of diphtheria. The Government of France had conferred high honors upon Roux for his investigations relative to diphtheria.

Dr. JOHN YOUNG BROWN, of Lakeland, read a paper entitled

SOME FURTHER OBSERVATIONS ON PELVIC DISEASE AND ITS RELATION TO INSANITY IN WOMEN, WITH REPORT OF CASES.

The author emphasized the importance of this subject and showed how gynecology and surgical work of every description had been neglected in the asylums of the South. In order to become familiar with this matter he addressed a circular letter to the superintendents of thirteen asylums of Southern cities, including those of Kentucky, requesting them to inform him what per cent. of the female population suffered from pelvic disease, and to what extent operative gynecologic work had been done. In reply, he received seven letters, the majority of which admitted that a large amount of pelvic disease existed among insane patients; others knew nothing about it and had never investigated the matter. A gentleman who has served for a number of years as superintendent of one of the largest Southern asylums, confessed to him that he was prejudiced against operative interference in these cases, he having seen so many of them recover, notwithstanding the existence of marked disease, in which he had expected to do some sort of operation. Dr. Brown then referred to the pioneer work of Dr. Geo. H. Robé in this direction, also that of Dr. Manton, who had urged that this class of patients be given the benefit of surgical interference which heretofore had been denied them. In discussing the relation of pelvic disease to insanity in women and the indications for operation, Dr. Brown wishes it to be distinctly understood that he only recognizes palpable disease as indicative of operative interference. He has very little faith in the theory of reflex neurotic troubles, without a lesion; nor does he believe that pelvic disease *per se* ever results in insanity. Dr. Brown then reported cases upon which he had operated for palpable pelvic disease, the operations being followed by relief of the mental trouble.

Dr. JOHN M. FOSTER, of Richmond, contributed a paper entitled "Diagnosis of the Presentation and Position of the Fetus by External Abdominal Examination." There had come under the author's observation within the last year twenty-seven obstetrical cases, twenty-three of which were in his own practice, the other four in the practice of other physicians. In all of his own cases he saw the patient from one day to one month before confinement and made a careful examination of the abdomen by palpation to determine the position of the child. In only one case was he in doubt as to the diagnosis on account of the great tension caused by the amniotic fluid. In the first nineteen cases he found a normal position and presentation, as was afterward verified at the delivery. But the twentieth case proved to be an occipito-posterior position. The four cases seen in the practice of other physicians had each advanced too far to hope to rectify the abnormal position for they were all abnormal; one case was an occipito-posterior position, delivered with forceps after much difficulty (stillborn fetus). One footling and two breech cases, all very protracted, with a stillborn fetus in all. Having outlined the

method of recognizing the normal position, the author then directed attention to a few of the leading points in the recognition of abnormal positions, saying that this was a subject the obstetrician must study for himself at the bedside in a practical manner. He urged giving obstetrical cases more attention before confinement, for by so doing we would reduce the infant, as well as the maternal mortality.

#### FIAT DAY—EVENING SESSION.

The Society met at the Harrodsburg Opera House, and was called to order at 8 P.M.

The PRESIDENT, Dr. MARVIN, delivered his Address, which was timely and listened to throughout its delivery with marked attention. Among the many things dwelt upon, he urged a more prompt publication of the Transactions.

Regarding the State Board of Health, some people had an idea that its work was simply to drive quacks out of the State. This was only a small part of its work. It has a higher duty to perform, namely, to educate the community in regard to sanitary science in order that "we may have life and have it more abundantly."

He then dwelt briefly on higher medical education and the four-year course, pointing out the great advantages and benefit to accrue from it, to both the profession and the public.

President Marvin also urged that a committee be appointed from the Society on Public Policy to work in conjunction with the State Board of Health in their efforts to protect the health of the people of Kentucky.

Dr. JOSEPH M. MATHEWS, of Louisville, followed with a popular address on "The Public Health." This address was well delivered, and punctuated here and there with applause. Dr. Mathews said in part that indiscriminate spitting in school rooms, hotels, sleeping cars should be regulated by law; that saliva, whether moist or dry, was a vehicle that brought danger and death. He then drew a picture of the consumptive in a sleeper going to the land of flowers for health, and the next day the health seeker for pleasure and recreation occupied the same berth and who, by want of cleanliness and proper hygienic prevention, was subjected to tuberculosis. In the cold northern climates much had been said with reference to transmitting the germ of tuberculosis by means of kissing, and for this reason he believed kissing was abolished in some places; but no Kentuckian had ever reached a point to forego the ecstasy and bliss arising from genuine osculation, and he would never advocate such a distressingly uncomfortable theory, although he was a firm believer in the germ theory of disease.

On motion of Dr. William H. Wathen, a vote of thanks was tendered to Drs. Marvin and Mathews for their able and instructive addresses.

Adjourned till 9 A.M. Thursday.

#### SECOND DAY—MORNING SESSION.

Dr. W. L. RODMAN, of Louisville, read a paper entitled

THE RADICAL CURE OF INGUINAL AND FEMORAL HERNIA.

At the present day, surgeons were more optimistic than they ever had been, and were doing a far greater number of herniotomies than was ever known in the world's history. The limits of the operation therefore are becoming enlarged rather than restricted: 1. operation for the relief of a strangulated hernia should, whenever practicable, be supplemented by a radical cure. 2. irreducible hernia, so-called, generally cause pain and gastro-intestinal symptoms, beside being more likely to be followed by obstruction, inflammation and strangulation, and these cases, as a class, should be subjected to a radical cure. 3. hernia accompanied with reducible hydrocele should be subjected to a radical cure. These cases will usually be found early in childhood, but he recently operated upon such a case in a young man, 22 years of age, living in La Rue County. Trusses and injections had failed to cure both the hernia and the hydrocele. The three classes already mentioned, without there be contra-indications, demand a radical cure.

Dr. Rodman then considered ordinary reducible hernia. Here many things are to be considered; age, occupation, position, general health. Children will be usually treated and successfully so by a suitable truss. He said that, according to high authority, children under 10 years of age are invariably cured by a truss. Recent statistics, however, taken from the largest hernia clinic known, the London Truss Society, show that according to McCreedy more than one-third of such cases are uncured by mechanical means.

The three operations having greatest popularity at the present time are in the order named; Bassini's, Halstead's and Macewan's operations. The Bassini method is by far

the most generally practiced, though it has been somewhat modified by different surgeons. Dawbarn, of New York City, makes quite a material modification of Bassini's operation in transplanting the testicle from the scrotum to a point just inside the internal ring behind the peritoneum. Considering the statistics made during the last five years only, we find an astonishingly small fatality following this operation. Bassini reports 560 successful cases of his operation without a death; Marcy did over 200 with no mortality; Macewan 81 cases without a death, and Coley did 200 operations with one death, and this was due to double pneumonia on the eighth day, the result of ether.

DR. FREDERICK P. HENRY, of Philadelphia, Pa., read a paper entitled "Remarks on Chlorosis and its Treatment." He said the chief predisposing causes of chlorosis are to be found in age, sex and constitution. The principal of these predisposing causes is, he believes, a congenital tendency to anemia. The exciting causes are those of anemia in general, such as insufficient food, light, air, and exercise, overwork, either mental or physical, anxiety, grief, and nervous excitement in general. The anatomic characters were next considered at length. The complications of chlorosis are phthisis, gastric ulcer, chorea, and exophthalmic goitre. As regards the treatment, the remarkable efficacy of iron was referred to when used in the initial stage. Nearly all chlorotics are dyspeptic, and until the digestive disorder is relieved the full benefit of iron can not be obtained. In cases of atonic dyspepsia, the simple bitters, such as gentian or exciters of the smooth muscular fibers, such as strychnia or brucia, may be administered before meals, or if there is gastric dilatation, naphthol, salicylate of bismuth, or chloroform water may be given three or four hours after meals, as recommended by Le Gendre, in order to limit or stop the abnormal fermentation generally present in that condition.

DR. LOUIS FRANK, of Louisville, read a paper on "Treatment of Puerperal Sepsis." The author first dwelt upon the etiology and pathology of this form of sepsis. Pre-existing gonorrhea may cause sepsis, as may any pathologic condition of the genital organs which antedates delivery. The conditions are often not discovered until too late to institute prophylaxis. Notwithstanding the fact that infection is most frequently conveyed by the hands, instruments, and dressings of the obstetrician or nurse, there may also be local conditions in the genital tract below the internal os which play an active part in permitting infection, and without which it would not occur. The treatment he considered under several heads: 1, those cases where the infection is the result not directly but indirectly of tears in the soft parts, there being a localized suppurative at these points; 2, those cases where septic endometritis exists; 3, where pus tubes or sacs in the broad ligaments are found; 4, purulent metritis and parenchymatous metritis; 5, purulent peritonitis; 6, sapremia, septicemia or pyemia.

DR. CURRAN POPE, of Louisville, read a paper on

#### SOME REFLECTIONS ON THE CAUSATION AND THERAPEUTICS OF NERVOUS DISEASES.

The medical mind has been recently directed toward the presence and excess of uric acid in the excretions of persons suffering from various forms of nervous troubles, and some French investigators go so far as to state that nervous diseases and uric acid are one and the same thing. This is based largely upon the investigations and statements of Haig and Bouchard whose experiments are marked by unexcelled brilliancy. Dr. Pope is constrained to believe, however, that the deductions therefrom are erroneous. He believes that the position assumed by Hertor and Horbaczewski is correct, and that uric acid largely derived from nuclein is the detritus of tissue waste and a resultant of nerve functioning; in other words, the presence of uric acid is an indication and a manifestation of nutritive and digestive disturbance. It is the result of nutritive disturbances going on in the body where so many minute, vito-chemic reactions take place.

Considerable experience in the treatment of all forms of nervous disease has taught the author, in many instances, that elimination must precede nutritional treatment, and he had seen few cases that had not been benefited by this line of treatment, strictly individualized in its application to the case in hand. In his opinion, hydrotherapy is by far the most satisfactory, pliable and useful remedy that the medical profession possesses, and after some years of experience with it he does not hesitate to say that he believes this agent, cautiously and carefully applied by a physician thoroughly trained in its application, to be the very best means for the

correction of disordered nerve force, the elimination of waste products, and the toning of the vasomotor system.

#### SECOND DAY—AFTERNOON SESSION.

The first paper read at this session was by DR. H. J. COWAN, of Danville, entitled "A Case of Monocular Albuminuric Retinitis—Recovery."

DR. J. MORRISON RAY, of Louisville, read a paper on "The Blind of Kentucky."

DR. HORACE H. GRANT, of Louisville, read a paper entitled "Comparative Value of Mechanical Devices in Making Intestinal Anastomosis," and DR. AUGUST SCHACHNER, of Louisville, one on "Modern Methods of Intestinal Anastomosis."

These papers considered all known mechanical devices for performing intestinal anastomosis up to date, and the deductions drawn incline to the belief that the day is not far distant when surgeons will return to the old method of suturing the bowel without the aid of mechanical devices.

DR. HENRY E. TULEY, of Louisville, read a paper entitled

#### THE CARE OF THE NEWBORN.

The question of the care and management of the newborn child has so long been relegated to ignorant mothers and nurses, that a consideration of the subject by medical men is opportune. The danger of septicemia threatens every newborn child through the medium of the cord. We know that tetanus, erysipelas and diphtheria occur in the young infant, the infecting organism gaining entrance through the cord. The cord should be tied in two places, about one inch apart, with a strong ligature which has been previously sterilized, extra care being exercised in tying those cords which contain a large amount of Wharton's jelly, as the shrinkage of this may cause the ligature to slip and a dangerous hemorrhage ensue.

Relative to feeding, it is hardly necessary to state that unless some physical condition precludes, all infants should be given nature's food—mother's milk. Immediately after birth the child should be anointed thoroughly with vaselin or olive oil, not with lard, on account of the salt which it contains, then wrapped in a shawl or blanket and laid away for at least twelve hours, before it is bathed and dressed and given to its mother for the first nursing. During the first six hours the cord should be examined frequently for hemorrhage. The child's temperature should be taken twice daily for at least one week after birth. Should the child be getting an insufficient quantity of milk it will have an elevation of temperature from 1 to 4 degrees above normal.

The important precaution to prevent thrush or sprue is the regular cleansing of the child's mouth before and after each nursing, which can be done by means of a cotton swab on the finger wet with a saturated solution of boracic acid. Instructions should be given for the proper care of the buttocks.

DR. M. F. COOMES, of Louisville, read a paper on "Stricture of the Esophagus." Strictures of the esophagus occur mostly in children, and were generally due to traumatism. Cases occur more frequently in the United States than in any other part of the world, for the reason that American housewives made use of lime; whereas in England, Germany and other countries they did not use it. American children got hold of this lime and swallowed it.

DR. GEO. S. DAVIS, of Salvisa, read a paper on the "Treatment of Pneumonia."

DR. J. G. CARPENTER, of Stanford, followed with a paper on "Abdominal Surgery in the Country." He said that Dr. John Craig, of Stanford, operated on a woman 30 years of age for an abdominal tumor in 1850. There was a large sac, containing many smaller ones, all filled with fluid, and the tumor weighed fourteen pounds. The abdomen was opened in the median line, and the tumor was a multilocular ovarian cyst. Similar operations were referred to as having been done in the country in farm-houses by Dr. Craig and his assistants. Dr. Carpenter said the best results in the past had been obtained in the country in farm-houses, out of hospitals, and by country surgeons, as had been claimed both by Price and Tait.

DR. GEO. BEELER, of Clinton, read a paper on "Milk Sickness," in which he reported several interesting cases occurring in the practice of himself and others. From the aggravated character of the disease, its successful treatment requires great discrimination and experience.

DR. S. G. DARNEY, of Louisville, read a paper on "Phlyctenular Ophthalmia."

(To be continued.)

Blank Applications for membership in the Association at the JOURNAL office. Write for them; sent free.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:  
PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JUNE 29, 1895.

GOITRE TREATED BY THE DESICCATED THYROIDS.

At the seventeenth annual congress of the American Laryngological Association just held at Rochester, N. Y., Dr. E. FLETCHER INGALS, of Chicago, read a paper on this subject, in which he presented the histories of fifty cases, recently treated by himself and others, with desiccated thyroids. An analysis of these cases and a consideration of the history of the use of the thyroid products in goitre and myxedema served to warrant the following conclusions:

Thyroid products produce marked physiologic effects upon the nervous and circulatory systems as indicated by headache, dizziness, pains in various portions of the body and great weakness; and by flushing of the face and rapidity of the heart's action. Some of these unpleasant symptoms usually occur when a daily dose is reached, corresponding to one and one-half or two entire thyroid glands of the sheep.

If the administration of the remedy in doses that cause such symptoms is continued for a few days, constitutional effects are produced indicating that persistent use of doses of from 6 to 12 grs. of the dried thyroid (equivalent to one or two thyroid glands) three times daily, might produce fatal results.

Desiccated thyroid glands appear quite as active and more stable than the liquid extract.

Internal administration appears quite as effective as hypodermatic medication.

For internal use the adult dose of the desiccated thyroids should not exceed 2 grs. three times daily, at first; but the dose may be gradually increased to two or three times this quantity, providing it does not cause unpleasant symptoms. There is no evi-

dence that moderate doses have an injurious effect.

The remedy in some cases has a pronounced effect on the body weight, but this is very uncertain and varies so greatly in different persons and in the same individual at different times that there is strong reason for suspecting that the loss of weight that sometimes follows this administration may be due entirely to disturbance of the digestive organs.

In the treatment of myxedema, the remedy has undoubted value and appears to benefit quite a large percentage. In these cases it is probable that the best results will be obtained by giving it at intervals for a long time.

In exophthalmic goitre the remedy causes rapid reduction in the size of the gland, but it has but little if any effect upon the exophthalmos, and it apparently aggravates the heart symptoms. In this disease it must be used guardedly, and its effects must be carefully watched.

In many cases of goitre, internal administration of full doses of the products of the thyroid is followed by a most remarkable diminution in the size of the diseased gland. Improvement or cure may confidently be expected in 76 per cent. of the cases, but sufficient time has not yet elapsed to determine what the final results will be. It is probable that cystic growths in the thyroid gland would not be influenced by this remedy.

Clinical experience has not yet demonstrated that this remedy is of value in other diseases, but its effect in diminishing the size even of very firm and hard enlargement of the thyroid gland would certainly justify experimentation in other directions.

QUININ OR ARSENIC IN CHOREA.

DR. PHILIP C. KNAPP writes, in the *Boston Medical and Surgical Journal*, that he has, at the City Hospital, given quinin a trial, not on an extended scale, according to the suggestion of Dr. H. C. Wood made in 1893 before the Association of American Physicians. The results of this trial were not so favorable as appeared to have been obtained by Dr. Wood, but in one case there occurred a complete recovery within a week, and in another within three weeks. But inasmuch as all choreas are not the same, nor from a like etiologic source, it is not unreasonable to suppose that quinin may serve as usefully as arsenic in a proportion of the cases.

DR. KNAPP did not feel sufficiently encouraged by this trial to extend it to his private practice. On this point and on the varieties of the affection he remarks as follows:

"Choreic movements are not uncommon as a result of structural brain disease, but they are rarely, if ever, seen as a symptom of diseases of the cord. In canine chorea, on the other hand, which is not proved to be the same as human chorea, the changes are chiefly in the cord. It is possible that in some

cases, such as those reported to the American Neurological Association in 1890 by WEIR MITCHELL, the morbid process may affect chiefly the cord, but such cases are rare.

"It is furthermore possible that in the future we may differentiate several affections which are now called chorea. HUNTINGTON's chorea and the electric chorea of DUBINI are now fully recognized as distinct diseases, having no connection with the ordinary chorea of childhood—SYDENHAM's chorea. Evidence is accumulating that in most cases of SYDENHAM's chorea we have to do with a disease of microbic origin, and the researches of BERKELEY, DANA and PIANESE have done much to confirm that belief. Other cases, including some of the rather rare cases which are alleged to be due to fright or to irritation, may be of hysterical origin. In chorea of microbic origin the toxin probably exerts its chief influence upon the brain cortex, especially in its motor region.

"The hypothesis on which quinin is recommended for the treatment of chorea seems to me untenable, and the therapeutic results are based thus far on too few cases to warrant us in ascribing greater virtues to this drug than to arsenic. Not having the idea at the time of publishing the results of this very imperfect trial of the drug, the results of one season's trial did not seem to me of sufficient value to lead me to try it in my private practice or in my subsequent terms of service at the hospital, and I went back to my former custom of supplementing the rest and regimen with full doses of arsenic, associated if necessary with iron or other tonics, and, in case of great motor disturbance and restlessness, with sulphonal or other sedatives."

#### OCULAR SYMPTOMS OF THE LITHEMIC STATE.

Lithemia is not latent or suppressed gout, it is a modified form of gout. It is the form which is particularly prone to manifest itself in this country, and has on this account been styled American gout by DA COSTA<sup>1</sup>, who by his writings has contributed largely to our knowledge of this peculiar morbid state. The term, lithemia, is not entirely satisfactory, since the condition intended to be described involves much more than a mere excess of uric or lithic acid in the blood or urine. The blood contains urates in excess and frequently oxalates, also other imperfectly elaborated products of waste, such as xanthin and paraxanthin; possibly it may yet be further poisoned, as suggested by the same authority, by the absorption of ptomaines, or toxalbumins, resulting from imperfect gastric and intestinal digestion. The urine is, as a rule, increased in density and in its content of coloring matter, and is acid in reaction; but spontaneous deposits of urates and of uric acid are seldom observed; small quantities of albumin may sometimes be found and even tube casts, both hyalin and epithelial, but these are only transitory and do not indicate permanent kidney disease. While a deposit of urates in the vicinity of the joints does not occur, and attacks of acute arthritis are rare, there is a painless enlargement of the phalangeal joints with

some impairment of function, especially observed in elderly people. The blood tension may be normal, or moderately increased in lithemia, but it is so to a less degree than in typical gout, and the arteries do not so readily tend to the atheromatous condition; neither do the heart or kidneys present the usual gouty changes. There is no acute exacerbation of joint inflammation in lithemia, as there is in true gout, such attacks, according to TROUSSEAU's teaching, being conservative and therapeutic efforts of nature to relieve the condition, but there are other disturbances which are not entitled to be considered so favorably.

Among the usual symptoms have been enumerated, impaired digestion and a tendency to acid or fermentative dyspepsia, muscular pains, neuralgic attacks, pains in the tendons, malaise and indisposition to exertion, drowsiness during the day, lack of ambition, depression of spirits, frequent and severe attacks of vertigo and migraine, restlessness, insomnia and jerking muscles at night. One consequence of defective oxidation and deficient elimination and of the excess of food supply, is that the functions of the liver are imperfectly performed and there is generally more or less hepatic disorder, with its attendant symptoms.

The ocular affections associated with lithemia have quite recently been reviewed by S. D. RISLEY of Philadelphia, in a paper read at the State Medical Society of Pennsylvania. Very much has been said and written, directing attention to eye abnormalities as the cause of irregularities of function in remote organs, producing symptoms which are liable to be mistaken for cerebral, gastric, hepatic, renal, spinal or nervous disease. Even chorea and epilepsy have been traced to this cause and cases have been effectually relieved by appropriately selected glasses.

It has also been shown *per contra* that general disorders having their principal lesions in the great nerve centers, like locomotor ataxia, or in the blood, as in syphilis and tuberculosis, or remote organs and tissues, as in Bright's disease of the kidneys, or in disordered metabolism, as in gout and rheumatism—may each give rise to characteristic changes in structure and disturbance in function of the organs of vision. Directly in this connection, RISLEY calls attention to the fact that lithemia is both a primary and a modifying factor in many ocular discomforts and even the efficient cause of many serious diseases of the eye. The great liability of gouty subjects to transient vasomotor derangements, to persistent and recurrent inflammations of mucous membranes and fibrous tissues, and to degenerative changes in vascular walls is generally recognized, and in its modified form, as lithemia, something of the same character might be looked for in an organ like the eye, in which these structures are represented in such a highly organized form.

<sup>1</sup> The Pathology of Lithemia, Medical News, March 17, 1895.

In the etiology of iritis, lithemia stands second only to syphilis in the number of the victims, while in obstinacy and tendency to recur it stands first. But there are other forms of ocular disturbance which are less well known than rheumatic iritis, or irido-cyclitis, as it is called, and in the treatment of which the same causative factor should not be overlooked. In such cases, local measures are useless and the patient will not begin to recover until the diet is regulated and the appropriate remedies given. Among these disorders is the conjunctivitis of children which is not infrequently associated with impaired alimentation and imperfect assimilation of food. In adults, also, conjunctivitis may have this origin, while episcleritis is a very common manifestation of lithemia.

Some disorders of refraction, producing weak eyes, and evidences of eye strain, which apparently admit of easy correction are found not to be much benefited by appropriate glasses. Such a patient may go from one clinic to another, until some one recognizes in the sedentary life and badly selected diet the efficient cause of an underlying lithemia, and directs the patient to the path which leads to recovery, both of vision and of health.

RISLEY declares that a large number of patients with habitually weak eyes, who receive glasses of low power for the correction of minor defects of refraction, are victims of this diathesis. They suffer from every attempt to use the eyes at near work, their symptoms being out of all proportion to the amount of abnormality which can be detected. Low grades of muscular anomaly, varying in kind and degree from day to day, may be observed. The ophthalmoscope reveals an injected nerve and choroid, but no gross change, except that if the patient be past middle life and the diathesis of long standing, there may be found well-marked striation of the retinal fiber layer and granular—or it may be, gray—borders to the retinal vessels, together with a cinnabar red and woolly eye ground. The symptoms may entirely disappear if the patients get a few days' outing, and they may then lay their glasses aside, owing to improved metabolism and increased excretion brought about by exercise. This of itself is indicative of the systemic origin of the symptoms, especially if the latter return upon resuming the former sedentary habits of life.

In well-advanced cases with general arterial changes, serious lesions may occur in the eye. Thus innumerable small apoplexies may be observed in hemorrhagic retinitis, even peri-vasculitis, hemorrhagic glaucoma, and the choroidal disease which precedes incipient cataract may be detected; the changes in the circulation in the eye going on progressively in association with those of the general vascular system. The importance of the early recognition of the real character of these changes is obvious,

and the information gained by ophthalmoscopic examination will enable the physician to institute appropriate measures to prevent the further progress of the disease or, at least, to materially delay its development. Some forms of corneal disease—glaucoma, hemorrhagic retinitis, albuminuric retinitis and peri-vasculitis should always lead to a careful analysis of the case, since they may prove to be but one of several groups of symptoms pointing to the general impairment of the vital functions attending the lithemic state. Incidentally, it is to be observed that the results of surgical operation in advanced cases, especially in elderly subjects, are greatly impaired by the presence of lithemia, and in cataract extractions, iridectomies and other operations, in such profoundly diseased eyes, the surgeon, if he is wise, will give a doubtful or a guarded prognosis.

#### GRAPHOLOGY.

PROFESSOR WM. PREYER, whose work in physiology and physiologic psychology is well known and highly valued, has recently published a work on the "Psychology of Handwriting," which is, for three-fourths of its volume at least, a treatise on graphology or the science or pseudo-science of determining personal traits and character from handwriting. Another prominent medical scientist, LOMBROSO, has entered the same field, and it may therefore be considered as not undeserving of notice, the more especially as it is, in the natural order of things, likely to attract popular attention and become more or less a fashionable fad of the day. Its literature is increasing and it has various elements of popularity. Its sanction or support by such eminent medical authorities goes far to render it respectable—in short, it seems to have a future, at least a temporary one.

The pathology of handwriting has an admitted importance and has been ably studied by ERMENEGILDO, GOLDSCHIEDER and others. PROFESSOR PREYER, however, goes farther and holds that its psychology must be studied by the physician, that the neuropathologist must examine the handwriting for character, simulation, emotional condition, etc. That there may be a germ of truth in this may be admitted, but there is a serious prospect of false diagnosis if this method is to be generally adopted and its results accepted according to the dicta of the graphologist. What are we to say of the ataxic, drunken-appearing signature of SHAKESPEARE, for example, to say nothing of many eminent men whose handwriting would indicate mediocrity, not to mention qualities positively vicious, according to the graphologic signs? Such examples can be found abundantly, and do not speak well for the accuracy of the indication.

Moreover, graphologists are not all in agreement as to the value of features, and one sees rectitude

where another might suspect deceit. The possible gross injustice that may thus be done, in individual cases, will be obvious to any one.

The fact is, handwriting is an artificial accomplishment and is affected by so many factors that a perfectly natural and characteristic one is probably more of a rarity than many would suspect. As an indication of character it is a dangerous guide and ought, at best, to be only used by especially skilled observers, who themselves should draw their own conclusions with reserve, and ought to hesitate before laying down formal directions for the guidance of others.

For medical purposes the study has a value, but more from a pathologic than a psychologic point of view, and the recommendation of its use should be limited to the study of its disorders in disease. The germ of truth that exists in the popular graphology of the day, is not enough to give the latter the rank of an accepted science, even with the support of high authorities like PREYER and others.

#### A RIVAL TO PERKINSISM.

"No wretch e'er felt the halter draw  
With good opinion of the law."

The State of "Missouri has a Still," says the *Medical Fortnightly*, "that never rests." It is DR. STILL, the so-called "Osteopath."

One of the down-trodden worms of this Still—JAMES STROTHERS—is located at Roseville, near Monmouth, Illinois. He issued a circular in the *Roseville Times*, May 3, 1895, in which he made the usual tirade of irregulars and miscellaneous rascals, generally, against the Practice of Medicine Act of Illinois, and the State Board of Health, on account of his arrest by that Board. This circular which sets forth the grievance of the "Osteopaths" was reprinted from the *Roseville Times* and distributed to the members of the Illinois Legislature. May 28, MR. HAMER introduced into the State Senate the following:

#### A BILL

For an Act to amend Section ten (10) of an Act entitled, "An Act to regulate the practice of medicine in the State of Illinois," approved June 16, 1887, in force July 1, 1887.

SECTION 1.—Be it enacted by the People of the State of Illinois, represented in the General Assembly, That section ten (10) of an Act entitled, "An Act to regulate the practice of medicine in the State of Illinois," approved June 16, 1887, in force July 1, 1887, be amended to read as follows:

SEC. 10.—Any person shall be regarded as practicing medicine, within the meaning of this Act, who shall treat, operate on, or prescribe for any physical ailment of another.

But nothing in this Act shall be construed to prohibit services in case of emergency, or the domestic administration of family remedies, or the practice of "Osteopathy," or to commissioned surgeons of the United States Army, Navy or Marine-Hospitals service in the discharge of their official duties.

The first three lines attracted no attention on the part of any reader and the affair was managed very quietly and actually passed the Senate, and but for the watchfulness of the Committee on Legislation of the Illinois State Medical Society, and DR. JOHN L.

WHITE, of the House, would have passed both houses without attracting any particular attention.

It seems that the original Osteopath, "DR." STILL, has a "college," the "American School of Osteopathy," located at Kirksville, Mo., from which emanate such hopeful worthies as STROTHERS.

DR. STEELE, of St. Louis, who investigated the matter, read a paper on the subject before the Missouri State Medical Society, of which the *Fortnightly* gives an abstract:

"The question is now often asked, What is osteopathy? It may be said to be a 'school of medicine' of which one STILL, of Kirksville, is the disciple, which has developed to such an extent as to have a 'college' from which numerous 'graduates' are being sent out; which has had a trial for a law of recognition, which bill passed both houses of the recent Legislature, and would have gone upon the statute books had it not been wisely vetoed by GOVERNOR STONE. All thanks to him for having saved the State from disgrace! The 'graduates' of this 'school' do not need any special training in anatomy, physiology or therapeutics, as the whole system is summed up in one proposition: all diseases are due to the displacement of bones and consequent pressure on nerves and other tissues. The summary of treatment is simplicity itself: reduction cures. There are two kinds of disease: 1, one from displaced bones of the extremities, causing deformities, pain, etc.; 2, the other, dislocation of some of the vertebræ, giving rise to trunkal diseases. But the same treatment cures all. The stock of knowledge, therefore, consists in the knack of manipulation, with perhaps an element of hypnotism—certainly a large amount of suggestion. In this, very like Christian science, certainly many cures are effected, the classes benefited being four: 1, old adhesions following sprains, rheumatism, etc., which can be broken up; 2, cases where there is really no pain or tenderness in a joint but the patient has lost its use through fear; 3, hysterical cases; 4, old dislocations, real. The regular profession has been derelict in not recognizing and curing such cases."

Osteopathy as it is practiced, thus appears to be massage, pure and simple, and DR. STEELE has not quite done justice to modern teaching, which recognizes fully the indications for massage and the correct methods of its application. The masseur has come to stay, but we do not like to see him masquerading under the name, osteopath. A masseur of the first order must thoroughly understand the anatomy of the body. Now-a-days when the masseur is as indispensable to the general practitioner and the surgeon, as the trained nurse, he is so much in demand that no excuse can be offered for his adherence to theories such as are propagated by this veriest moonshiner of all the illicit stills in the country. Let the masseur stick to his art.

#### RAILWAY ACCIDENTS AND MORTALITY.

From advance sheets of the "Abstract of Statistics of the Railways of the United States" for the year ended June 30, 1894, we learn that, "during the year

1,823 railway employes were killed and 23,422 were injured, as compared with 2,727 killed and 31,729 injured in 1893. This marked decrease in casualty is in part due to the decrease in the number of men employed, and the decrease in the volume of business handled. The increased use of automatic appliances on railway equipment also may have rendered railway employment less dangerous and it may be that the grade of efficiency of employes has been raised.

"The number of passengers killed was 324, an increase of 25, and the number injured was 3,304, a decrease of 195. Of the total number of fatal casualties to railway employes, 251 were due to coupling and uncoupling cars, 439 to falling from trains and engines, 50 to overhead obstructions, 145 to collisions, 108 to derailments, and the balance to various other causes not easily classified. To show the ratio of casualty, it may be stated that 1 employe was killed out of every 428 in service, and 1 injured out of every 33 employed. The trainmen perform the most dangerous service, 1 out of every 156 employed having been killed, and 1 out of every 12 having been injured.

"The ratio of casualty to passengers is in striking contrast to that of railway employes, 1 passenger having been killed out of each 1,912,618 carried, or for each 44,103,228 miles traveled, and 1 injured out of each 204,248 carried, or for each 4,709,771 miles traveled. A distribution of accidents to the territorial groups exhibits the diversity in the relative safety of railway employment and of railway travel in the different sections of the country."

## CORRESPONDENCE.

### Utah State Medical Society.

SALT LAKE CITY, UTAH, June 18, 1895.

To the Editor:—In February of the present year, a Utah State Medical Society was organized, its members comprising almost all of the best known physicians in the Territory. The Code of Ethics of the AMERICAN MEDICAL ASSOCIATION was adopted. The first annual meeting will be held Oct. 1 and 2, 1895. The following is a list of officers elected: President, F. S. Bascom, M.D.; First Vice-President, Walter R. Pike, M.D.; Second Vice-President, G. M. Perkins, M.D.; Secretary, J. N. Harrison, M.D.; Treasurer, G. M. Wilson, M.D.

J. N. HARRISON, M.D., Sec'y.

### A Question of Translation.

WHEELING, W. VA., June 19, 1895.

To the Editor:—In the Correspondence column of the JOURNAL, I notice a letter by Dr. Chas. G. Kuhlman with the heading, "*Audi Alteram Partem*." I note a very serious mistake. At the close of his letter the Doctor correctly quotes Binz, as stating in 1883 at the Buda-Pesth Congress for Internal Medicine: "Our future therapeutic efforts in infectious diseases must be toward '*Denlebenden organismus zu entgiften*.'" This he translates, however, in parenthesis: "To poison the organism, as it were." But, *entgiften* means just the opposite, viz., to remove or eliminate poison. Therefore Dr. Kuhlman has no reason to take issue with Binz on this doctrine, as they are both of the same opinion as the majority of the American medical profession, who will "continue in the future as they have done in the past—to eliminate the contagium at the bedside." It is sometimes dangerous to make a translation when not perfectly familiar with the respective languages.

Respectfully, G. A. ASCHMAN, M.D.

## BOOK NOTICES.

**On the Symptoms which Simulate Diseases of the Pelvic Organs in Women, and Their Treatment by *Allo-piosto-Myo-Kinetics* (Massage), and by *Auto-Piosto-Myo-Kinetics* (self-movements of muscles under pressure).** By A. RABAGLIATI, M.A., F.R.C.S., Ed., Honorary Gynecologist, late Senior Honorary Surgeon, Bradford Infirmary. Octavo, illustrated by six full-page heliogravure plates, extra muslin, pp. 77. Price \$1.50. New York: William Wood and Company. 1895.

Those who have in *propria persona* experienced the full benefits of massage, as demonstrated on a debilitated and plethoric body, will, we feel sure, yield to the enthusiastic masseur and masseuse the meed of praise to which they are entitled. But there must be some limit even to the uses of massage. We may concede that massage is the very best form of administering concentrated exercise, and that wherever and whenever exercise may be beneficial, massage, its "concentrated extract," is indicated, and yet we must deny that massage can prevent microbic invasion, arrest malignant disease, or restore lost parts.

We, however, freely concede that adhesions may be broken up, that circulation may be improved, and neuritis relieved by proper use of massage. And there is little question but many cases treated in the past few years by oöphorectomy would have been better treated by rational massage, and self-movements of muscles, as advocated by our author. The book is interesting and valuable.

**Transactions of the American Association of Obstetricians and Gynecologists.** For the Year 1894. Vol. VII. Octavo, cl., pp. 520. Philadelphia. 1895.

We have already published in this JOURNAL a full account of the last meeting in Toronto of this flourishing society, and given abstracts of the papers. It only remains, therefore, to chronicle the appearance of this handsome volume, which makes the seventh of an interesting series, and adds to the current literature very much that is of permanent value. The volume is larger than its predecessor, and its typography is excellent.

**The Care of the Baby.** A Manual for Mothers and Nurses, containing Practical Directions for the Management of Infancy and Childhood in Health and Disease. By J. P. CROZER GRIFFITH, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Octavo, cl., pp. 392. Price \$1.50. Philadelphia: W. B. Saunders. 1895.

To the already large number of guides to mothers and nurses, this treatise has been added. There are eleven chapters written in popular style, and fairly illustrated. The physician may find it convenient to recommend a book to his patients, and this of Dr. Griffith seems to meet the want. Many a baby will be better cared for when the mother becomes familiar with the contents of this book. We commend it.

**The History of Prostitution, ITS EXTENT, CAUSES AND EFFECTS THROUGHOUT THE WORLD.** By WILLIAM W. SANGER, M.D., Resident Physician, Blackwell's Island. With numerous editorial notes and an appendix. 8vo, cl., pp. 709. New York: The American Medical Press. 1895.

The investigation of which this book is the outcome was begun in 1855, and completed in 1858. An appendix brings the results down to date. The author arrives at the only conclusion to which an unprejudiced mind can come after careful investigation, namely, that the evil, which has existed in all ages, can not be totally suppressed by any legislative measures whatever, that its calamitous results may be diminished by proper regulation, and that the number engaged in prostitution may be measurably diminished by increasing the opportunities for respectable employment, and that so far from discouraging the employment of women in the

shops and lighter trades, that every encouragement should be given to dependent young women to engage in such pursuits.

The usefulness of this book is most apparent to those engaged in the work of public charities and corrections, and the civic legislator may here find many precedents to guide him in his search for a remedy for the present rather depressing state of things as shown by municipal statistics.

**Atlas of Clinical Medicine.** By BYRON BRAMWELL, M.D., Assistant Physician to the Edinburgh Royal Infirmary. Vol. III, Part 2. Edinburgh: F. and A. Constable, University Press. 1895.

The second part of the third volume of this excellent work in clinical medicine has just appeared. Like its predecessors, it is a very interesting number, dealing with congenital syphilis, progressive muscular atrophy, the progressive muscular dystrophies, points to be observed in the clinical examination of cases of pseudo-hypertrophic paralysis and other forms of progressive muscular dystrophy, and notes of cases of pseudo-hypertrophic paralysis and other forms of progressive muscular dystrophy.

There are ten plates, with numerous illustrations of the text. Two of ichthyosis, one of multiple cancer of the breasts and other organs, four of congenital syphilis, two of progressive muscular atrophy, and one of cyanosis. In addition, there are numerous illustrations scattered through the text.

It is one of the best numbers issued in this useful work.

## PUBLIC HEALTH.

**Leprosy in Norway.**—According to the most recent statistics, furnished by Dr. E. Kaurin of Molde, leprosy is disappearing more and more in Norway. In 1856 there were about three thousand lepers in that country; at the end of 1892, there were not over eight hundred or nine hundred, half of whom were inmates of the leper asylums. Since then the number has so much decreased that it is proposed very soon to close two of the five asylums in the country. The author's opinion is that leprosy is an exclusively contagious affection and that heredity is not to be regarded as a predisposing cause. Strict segregation of lepers is, he believes, absolutely necessary in order to stamp out disease.<sup>1</sup>

**Prophylaxis of Paludism.**—Noel, after passing in review the successes and failures of quinin and certain of its salts in the prophylactic treatment of malaria, reaches the following conclusions: 1, the prophylaxis of paludism by quinin is a demonstrated fact; 2, there are no inconveniences attending the treatment in health, and quinin loses none of its efficacious properties in cases of intermittents; 3, the hydrochlorate of quinin is the best salt to use; 4, the drug should be taken each morning after arrival in the dangerous zone and during its passage; 5, the minimum daily dose is 0.30 grams. For troops on the march the pill form is preferable, but for those in camp it is better to use the medicament form an ingredient of a tonic. Notwithstanding the efficacy of quinin, in the light of recent knowledge that malaria is waterborne, the true prophylactic is pure water.<sup>2</sup>

**Cholera and Life Insurance.**—Dr. Oertel, the German bacteriologist, who died in Hamburg in September, 1894, from "laboratory cholera" had his life insured in favor of his mother. It will be remembered that the Doctor contracted the disease in the course of his experiments, but it was never possible to exactly determine the manner of infection either before or after death. The policy read that the amount was to be payable in case of "violent and sudden accident, inde-

pendent of the will of the assured, and determined by an external mechanical cause." After the Doctor's death the company refused to pay the policy and the matter was referred to the Hamburg Court of Appeals, which has decided that "the multiplication of the bacilli and the effects which these produce on the stomach and intestines are to be regarded as a chemical and not a 'mechanical' action."<sup>1</sup>

**Vaccinal Dermatoses.**—The dermatoses of vaccinia, no matter what their morphologic differences—erythematous, papular, vesicular, pemphigoid—agree in appearing from the ninth to the eleventh day, according to Hervieux, or on the eighth day according to Dauchey. In certain cases the eruption may appear earlier or, on the contrary, it may be later. The eruption appears without any modification of temperature; it is ephemeral, never contagious and rarely itches. These vaccinal eruptions are rare, they are nearly always observed in children, exceptionally in adults, and are more frequent in summer than in cold weather. Hervieux thinks they are due to the virus, and Behrend ascribes them to individual idiosyncrasy. While this question is still disputed, the influence of individual predisposition is undeniable. The pathogeny of these dermatoses is not yet well established. Some authors, as Morris, attribute them to reflex nervous action; others, as Behrend, claim they arise from the passage into blood, either of the vaccine virus itself, or from pus microbes from the pustules or their soluble products. The most frequent eruptions are a rash, of which Conget distinguishes four varieties—erythematous, morbilliform, papular and nettle-rash. Vaccinal malaria is equally frequent. Pemphigus is rare as is also purpura. It is interesting to note that while some skin lesions, like eczema and psoriasis, are favored by the development of vaccinia, the latter does not produce them but only encourages their development.<sup>2</sup>

**A State Vaccine Farm.**—The Illinois Legislature at its last session passed the following:

An Act to establish a Vaccine Laboratory and making an appropriation therefor.

SECTION 1.—*Be it enacted by the People of the State of Illinois, represented in the General Assembly, That the sum of three thousand (\$3,000) dollars be hereby appropriated, out of funds not otherwise appropriated, for the purpose of establishing, equipping and maintaining a laboratory in connection with the State University at Champaign, for the propagation of pure vaccine virus.*

SEC. 2.—*That the Trustees of said University shall have the management of said institution, Provided, however, that the State Board of Health shall exercise supervision of the methods of propagation and shall certify to the purity of all products.*

SEC. 3.—*That the product of the vaccine laboratory shall be furnished all physicians and Health Officers, within the State at the cost of propagation.*

SEC. 4.—*That a report of the management, together with a statement of the receipts and disbursements, be made and included in the annual report.*

The passage of this Act is one of the measures which the Legislative Committee of the Illinois State Medical Society advocated and pushed. The State Board of Health also commended the bill, but the active efforts of Drs. John L. White, of the Legislature, Graham of Chicago, and Maxwell of Mt. Carmel, alone secured its passage.

**Health Reports.**—The following health reports have been received by the Supervising Surgeon-General M.-H. S.:

### SMALLPOX—UNITED STATES.

Arizona: Nogales, June 17, 4 cases, 1 death.

Michigan: Detroit and Olivet, smallpox reported present June 8 to 15.

Missouri: St. Louis, June 8 to 15, 3 cases, 1 death.

Tennessee: Memphis, June 8 to 15, 2 cases.
